Hamilton, Ont.—The Provincial Board of Health has granted the city's application in regard to waterworks extensions. An expenditure of $127,000 on new pumps at the Beach station is now authorized without reference to the ratepayers.

Swift Current, Sask.—Tenders will be received until June 19, by the City of Swift Current, for one Motor-Driven Centrifugal Pump having a capacity of 800 Imperial gallons per minute against a 300 ft. head. Geo. D. Arnott, City Clerk.

Port Dover, Ont.—A water works system and sewage system are being considered for Port Dover, the approximate cost being put at $65,000. It is likely that a by-law will be submitted to the people in August next.

The **McCord Mfg., Co.,** has been granted an Ontario provincial license to manufacture motors, engines, and machinery of all kinds. The capital is not to exceed $50,000 and the company's attorney is A. R. Bartlet of Windsor, Ont.

Edwin S. Woods & Co., has been incorporated at Ottawa with a capital of $40,000 to manufacture railway supplies, engines, boilers and machinery of all kinds at Montreal. The incorporators are L. A. David, L. P. Grepeau and S. H. R. Bush all of Montreal.

Regina, Sask.—According to information received here, the Federal Governments will expend $300,000 in developing the lignite fields of Saskatchewan at Estevan. The development of those fields will solve the fuel question of this Province, it is believed, and prevent coal famines that have caused so much inconvenience during the past few winters..

A. G. Norris, transmission expert, with the S K F Ball Bearing Co., Hartford, Conn., will spend about three months in Canada on behalf of this concern and in co-operation with the Canadian Fairbanks-Morse Co., who are the sole agents for Canada for the S K F transmissions. Mr. Norris will work on transmissions only and divide his time between the Montreal and Toronto territories.

Hamilton, Ont.—Manager Sifton, of the Hamilton Hydro Commission, has recommended to the Hydro-Electric Board that a $12,000 electric plant be installed upon the premises of the Dominion Steel Foundry. He said that company was now demanding 600 or 700 additional horse-power, and that the installation of a sub-station at that plant would defer the construction of the contemplated sub-station on Trolley Street about two years. The latter would cost $35,000, he declared. The board will consider the proposition.

CATALOGUES

Power Machinery.—MacGovern & Co., New York, have issued a list of used power plant and electrical machinery and contractors equipment, etc.

Vaughan Flow Meter.—A bulletin issued by the Spray Engineering Co., Boston, Mass., illustrating and describing the Vaughan flow meter which is a simple and efficient instrument for indicating the flow of liquids in pipes.

Cooling Water For Ice Plants.—Bulletin dealing with economy cooling circulation water for ammonia or steam condensers by the method of spraying. Issued by the Spray Engineering Co., Boston, Mass.

SKF Ball Bearings.—A pocket list of ball bearings issued by the Canadian SKF Co., Toronto, contains primarily a series of tables giving the dimensions, maximum loads and prices of different sizes of bearings covering all types. Other matter includes illustrations of radial and thrust ball bearings and also a brief description covering the constructional features of the SKF bearings.

Duriron, a non-corrosive metal, is the subject of Bulletin No. 100, recently issued by the Duriron Castings Co., Dayton, Ohio. The bulletin first describes the chemical and physical properties of "Durion," which is of acid, alkali, and rust proof metal. The succeeding pages contain illustrations and descriptive matter covering "Duriron" standard pipe, drainage pipe, fittings, valves, cocks, pumps, blowers, etc. The concluding pages show illustrations of miscellaneous equipment such as tanks, condensers, stills and kettles, etc.

Progress in Water Works Pumps is the title of a catalogue issued by the De Laval Steam Turbine Co., Trenton, N.S., and compiled from the company's records. The catalogue contains a great deal of interesting information relative to development and advantages of steam turbine driven centrifugal pumps for city water supply covering the chief requirements for such installations and the suitability of these pumps for this class of work. An interesting feature of the catalogue consists of a number of brief descriptions of important municipal installations in Canada and the United States, together with half-tones showing the layout of each plant. Copies of this catalogue may be obtained on application from the Turbine Equipment Co., Toronto, Ontario.

Cameron Babbitt Retainer

(Patented in Canada and the U.S.A.)

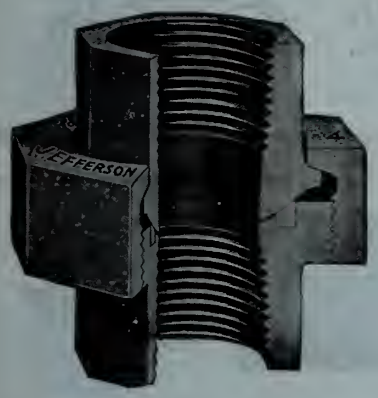
Not like clay or other material, as it does not stick to the work or hands. Does away with using leather or paste-board at end of box. For any metal.

The only satisfactory compound for retaining molten metal and can be used over and over again for months—no deterioration.

For prices and samples apply to

A.S.K. Chemical Company, Elora, Ontario

Yes, Sir, it's a mighty important feature—that brass seat ring



Don't overlook the fact that the brass-to-iron seat makes a corrosionless joint—but different from most unions you will see that here it is set back in a little recess—away from the run-way and pipe contents. The expansion and contraction of the balance of the union cannot loosen it from its embedded position. That's one of the reasons that

Jefferson Unions

mean union satisfaction. Then the shape of the joint. Note it is like a section of a ball—not cone shape. And it is ground carefully and accurately—insuring a tight joint that stays tight.

If you seek pipe line efficiency in your plant, hook up with Jeffersons—everywhere.

Write us to-day for a Jefferson Book—it shows the various types and dimensions.

There's a jobber near you who can supply you with Jeffersons in all sizes and styles. Write us for his name.

Some Jefferson Styles

Union Tee, with union on the outlet. Made also with male end on outlet.

Union Elbow, an economizer of the most pronounced type. Also made all female.

All Male Union. Saves two pipe joints between two female threaded parts.

Some Jefferson Features

The ground ball seat which insures a permanent tight joint; the patented brass-to-iron joint which prevents corrosion; the fact that they are the heaviest unions of their class made, and many other points that make for long, hard service.

With the cost of fuel steadily going U-P, how much of the 49% WASTE are You accounting for?

Modern Mining, with its elaborate machinery and much altered labor charges, is gradually forcing coal prices up and up. The day of cheap coal is becoming a thing of the past.

It is well known among engineers generally that if only 50 per cent. of the total preventable losses in steam boiler operation in this country could be saved, the total savings would go a long way towards paying the interest on the National Debt. And yet, careful investigation shows that the average plant is WASTING anywhere from 5% to 25% of its fuel—ALL of which could be recovered with the proper apparatus!

Central Station plants, selling their power as a commodity, for a profit, had this fact forced upon them several years ago; the average isolated plant, still under the domination of the non-technical "front office," continues to pile up higher and higher costs.

Many of these plants have spent thousands of dollars trying to eliminate the 5 per cent. engine-room losses. Isn't it about time to put nearly as much effort and intelligence into eliminating the 86 per cent. losses (preventable) that occur between the coal pile and the engine?

35% of the PREVENTABLE Fuel Waste Can Be Recovered with a Dean Cleaner

One-third of the total loss (preventable) is due solely to SCALE. This loss can be eliminated if the boiler tubes are cleaned regularly and thoroughly. That's where most boiler tube cleaning methods and devices fall down hard. To secure the most thorough results, use the Dean Cleaner. It has proven its superiority in this respect in direct competition with all other cleaning methods.

In one plant, its use permitted the engineer to operate four instead of five boilers—a 20% saving! In another, the coal consumption was cut 9%. In a third, the Dean increased steaming capacity 33 1-3%!

The Dean can—and will—do equally as well for YOU.

Try a Dean—FREE—At Our Expense

If you want to meet those rising costs—if you want to reduce your preventable losses to a minimum—ask us to send you a Dean Cleaner for Free Trial. Tell us the size of your tubes and type of boilers—we'll do the rest. We don't want you to buy the Dean—just try it—and then, if it can't convince you on its own merits, ship it back to us.

A trial of the Dean will do you no harm—and may do much good.

TRADE MARK

MAGNOLIA ANTIFRICTION METAL

TRADE MARK

FOR FERTILIZER GRINDERS

AGRICULTURAL CHEMICAL WORKS
901-903 Macy Street,
Los Angeles, Calif. 10/7/16.

Magnolia Metal Company,

Gentlemen: Referring to your inquiry regarding Magnolia Metal would say that the same is satisfactory in every way and does all you claim for it. Since we began using this brand we have had practically no trouble with hot bearings, and can recommend it as the very best for high speed machinery.

We are running a fertilizer grinder at the rate of 1500 revolutions per minute, which at times creates considerable dust, and have had no occasion to re-babbitt the bearings since the last two years. This surely speaks for itself.

Yours truly,
AGRICULTURAL CHEMICAL WORKS,
By L. Baruch, Sec'y.

PRACTICAL ENGINEER POCKET BOOK:

"I have about 25 Davis Traps of various sizes in service, the majority of them for 22 years. I will gladly recommend them at all times," wrote H. F. Hustedt, Chief Engineer, Tulane University, New Orleans, when ordering his first repairs.

Possibly all Davis Traps would not last that long without repairs. Much depends on the operating conditions. On some installations they last longer than on others. But all Davis Traps have Tobin Bronze seats and valves—a hard, tough metal from which long service may be expected.

And when these vital parts of the trap do wear out, they may be easily renewed at slight expense.

We make Pressure Regulators . Balanced Valve . Float Valve . Steam Trap . Back Pressure Valve . Exhaust Relief Valves . Stop and Check Valves . Pump Governors . Damper Regulators . Radiator Air Valves . Emergency Stop Valves.

Mechanical Regulation of Boiler Feed Water

By the use of the "S-C" method you are assured of a continuous feed at all times load is on boiler. The graduation in rate of feeding is entirely dependent upon the load and fire conditions. The Regulator will carry a constant level on steady load—higher level on light load and lower level on peak loads. Variation in water level is entirely dependent on inclined position of generator which is adjustable while operating under full load.

Bulletin No. 80 explains all.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled hearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

COE TURBINE BLOWER

ONE of these Blowers under each of your boilers will give you pressures you never saw before. It will do it efficiently, economically, and receive the full approval of authorities.

The COE TURBINE BLOWER slashes coal hills. It enables you to burn cheap fuel with minimum smoke, high CO2 results, complete combustion. It will give you a flexible fire, always under your control, ever ready to respond to peak load demands. Your Recorder will write a story of better, steadier steam pressure the day you install this wonderful machine.

The COE TURBINE BLOWER is well made. The best material goes into its construction. It is built to stand up and give service week-in-and-week-out, and never require so much as a minute's attention. In fact, the best way to care for a COE TURBINE BLOWER is to LEAVE IT ALONE.

IN RUSSIA

—millions of feet of Heating, Drying and Cooking Steam Lines are drained by the

Morehead
Back to Boiler
SYSTEM

With the industrial awakening of Russia came the introduction of the Morehead Back to Boiler System —it has been adopted as standard equipment in hundreds of leading Russian plants.

This world-wide supremacy of the Morehead System of Steam Drainage and Boiler Feeding is backed up by the judgment of the progressive American concerns who have been using the Morehead System for years.

If you use steam in any way for any purpose you can save money and speed up production by adding the easily installed and comparatively inexpensive Morehead System to your boiler room equipment.

Tell us about conditions in your own Plant and our engineers will make some practical suggestions on cutting the cost of your fuel.

MacLean's Magazine
FOR JULY

The Smugglers were Caught

THE true and complete story of a huge smuggling conspiracy which robbed the Canadian and United States Customs Departments of hundreds of thousands of dollars, and which was finally exposed by a Canadian Customs officer, is well told in the July MACLEAN'S. The parties concerned settled by handing over a huge check to the Canadian Government and not a word of the story has ever before been in print. The man who writes the article, J. D. Ronald, was personally concerned in the investigation, and he tells the whole case from first to last, merely changing the names of some of the central figures. This is one of the most striking special features that MACLEAN'S has ever had.

Confederation
the dominant theme of July MACLEAN'S

THE Jubilee of Confederation has led the Editor to make the July MACLEAN'S retrospective and interpretive of Confederation in the character of its main contents—this to meet the certain need and desire of the Canadian people. Note the fine provision of special Confederation article and features:

"THE MEETING OF MACDONALD AND BROWN."
By C. W. Jefferys, a frontispiece painted for MACLEAN'S.

'THE STORY OF CONFEDERATION."
By Thomas Bertram. A colorful narrative of the bringing about of the union of provinces.

"FIFTY YEARS OF BUSINESS EXPANSION."
By W. A. Craick, covering all phases of business—banking, insurance, manufacturing, agriculture, transportation, etc.

"THE BUILDING OF THE C.P.R."
By C. H. Mackintosh, former Lieutenant-Governor of the North West Territories, and an ex-editor of the Ottawa Citizen.

"CONFEDERATION AND AFTERWARDS."
By Agnes C. Laut. An article on Confederation and the taking over of the North West Territories from the Hudson Bay Company.

"SOME CANADIAN CONTRASTS."
By Frank Yeigh. A sketchy article showing some of the most picturesque ways in which Canada has advanced during the last fifteen years.

Look for this symbolic cover design in three colors at book stores and news-stands. It is a fine bit of work, and worth preserving.

"THE DRAFT."
By A. C. Allenson. A story of the part which Canadians took in the American Civil War.

MESSAGES ON CONFEDERATION
appear from the Premiers of many of the Provinces of Canada.

Billy Sunday Contributes:

"WHAT I THINK OF CANADA."
A brief article in the crisp, epigrammatical style of the famous evangelist, illustrated by some of his most recent photographs taken in action in New York.

The Fiction Features:

"THE GUN BRAND."
By James B. Hendryx. An interesting instalment of this exciting serial.

"THE OUTLAW BOAR."
By Clark E. Locke. A short story.

"PUTTING IT OVER."
By Hastings Webling. A golf story.

"THE CAPTAIN OF THE SUSAN DREW."
By Jack London. The first instalment of a two-part story—one of the last that London wrote.

The Best Number of MACLEAN'S

THAT has ever been put out is this July issue. It will be bigger, the articles are by long odds stronger, the stories more entertaining, and the illustrations more varied. Stephen Leacock's "Sunshine in Mariposa" is continued in this issue; also the regular Departments, Records of Success, Review of Reviews, The Business Outlook, and Information for Investors.

At All News-Dealers 15c.

"Fairbanks Valves Are My Choice"

Such is the opinion of every engineer who has given them a fair test. They are conservatively made; are heavier than the corresponding standard and heavy weights.

They are built to give the utmost service, and are fitted with

Renewable Bakelite Discs

These discs can be replaced in less than a minute, without removing the valve from the line, and without the use of a single tool except a wrench to unscrew the valve bonnet. Bakelite Discs have been proven by many experiments to have the longest life of any disc on the market.

They will stand the hardest usage, and most severe conditions of wet or dry steam.

The valve stems are packed with "Palmetto Twist."

Prices on application.

It's Safer, Cheaper and More Efficient

Sound and substantial reasons for replacing common straight tube heaters with the—

ALBERGER Multi-Head Heater

DOUBLE FLOATING HEAD

This is a big feature of the "ALBERGER" and eliminates the danger of expansion strains, a serious problem and a menace in other heaters. These floating heads are in sections so as to differentiate between expanding and contracting of tubes of different temperatures.

CUTS DOWN THE COSTS

The Helical Spiral corrugation gives the water a whirl in the ALBERGER HEATER, keeping tubes clean and free from scale. An increase of 50% in heat units is gained over common types of tube heaters thereby. Corrugated Copper Tubes eliminate formation of scale and prevent splitting, common with brass tubes.

Largest of plants are using the "Alberger" exclusively because it is found safer, cheaper, and better in every way. Write for full details.

TOOL COMPANY.
COLBURN MACHINE TOOL CO.
2
About a year ago, when we decided to build an addition to our plant, the matter of furnishing power became a serious problem on account of the fact that our power plant was already overloaded and we did not at that time want to install any more power units.
After compiling considerable data we decided to equip our new addition with S.K.F. ball bearing line and countershaft hangers. The self aligning feature of S.K.F. bearings appealed to us as being superior to other makes. We were greatly pleased with the results obtained from this installation, and immediately put in hangers on one of our old line shafts; also countershafts for large grinders and automatic screw machines, with the result that after adding considerable new, heavy machinery, we are experiencing no more trouble with our power plant, having ample capacity to run our shop 21-3/4 hours per day.
The actual saving on a large Landis grinder countershaft is 50%, others running from 20 to 40%, and line shaft from 15 to 25%. These savings were all proven by actual motor tests.
We estimate that the saving in cost of maintenance, and shut downs, due to hot and worn out bearings alone, will pay for the installations in a few years time. Had we not adapted this method of saving power, it would have meant the purchase of an entire new power unit, costing several thousand dollars.
We are replacing all line and countershafts with S.K.F. hangers throughout our plant as rapidly as we can arrange to put them in.
Yours very truly,
COLBURN MACHINE TOOL CO.
Treasurer.

GRATON & KNIGHT

Standardized Series LEATHER BELTING

Tanned by Us for Belting Use

What is Standardized Belting ?

Standardization of Graton & Knight Belts is not new. They have been standardized for many years.

They have been standardized on the basis of the work to be done—not made to meet theoretical specifications, laid out on paper for belt-makers to follow blindly.

During 66 years of actual usage these belts have survived and evolved into recognized, practical standards. And because they have evolved on the job, they have gradually become fitted to each kind of belting job.

There is a brand for every need—a complete and adequate Series of Standardized Belts. Each Brand is uniform as to tannage, strength, weight, performance—and each roll of each Brand.

Standardize the buying of your belting—and learn why it is so easy, so practical, so safe to merely specify "Graton & Knight—or equal."

Write for a description of Graton & Knight Standardized Brands and a copy of their book on belting. Or let them send a representative who will tell you about Belting Standards.

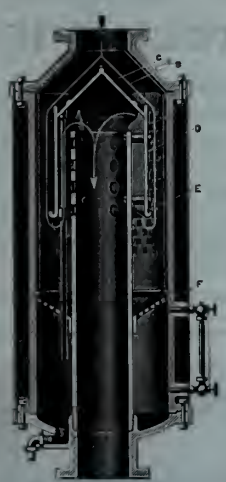
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

"I always ran my belts tight, George. This Cling-Surface keeps you busy puttin' it on."
"No, Uncle—I go over my belts now only once a month"

WE stood and watched him.

Above and on all sides of us the belts were moving: large and small, vertical and horizontal, quarter-turn and cross belts; each moving swiftly, silently.

There seemed to be thousands! And the Superintendent had told us that this ONE MAN took care of them all! We stood and watched him.

He carried a pail, and a stick wrapped at one end with a cloth bandage. Dipping this into the pail he carefully wiped the excess off upon the edge and laid the stick against the face of a moving belt. As he worked it back and forth we saw a light stain appearing on the pulley face. He was watching this also, for apparently satisfied, he stopped the treatment and went on to the next belt.

So that was all? A dip, a wipe and a few passes back and forth across the belt face? But how long would it last?

"That belt," said the Superintendent, "is now in such fine condition that it will not require any more CLING-SURFACE for a month. It is quite pliable, waterproof and practically oilproof, and what is more important still, it never slips even under the peak load. You see it is running very slack—we haven't had to take it up for three years.

"Before I had the shop use CLING-SURFACE we ran all our belts tight, and were having trouble every day. It kept four men busy just taking up belts, and applying belt dressings, but now this one man with the new semi-liquid CLING-SURFACE treats them all."

* * *

That is the NEW way to apply the NEW semi-liquid "easy-to-use" CLING-SURFACE. It requires no heating in ordinary temperatures. It results in a money saving more than covering the cost of the CLING-SURFACE required.

The plan 10,000 firms have found successful will interest you. Let us send it free, with any special service your conditions may require.

Remember, use CLING-SURFACE and you won't need belt dressings.

For Solid Pinions:

THE Morse Chain Company 1917 Diary is a diary in name only, the memorandum pages not being dated as in previous year. The book therefore does not get out of date as the year draws to a close.

Eighty 2½ by 4¼ plain ruled pages, in addition to 48 pages of MORSE Chain Data and Illustrations, bound in genuine black leather, make a book but ¼ inch thick and just the right size for the vest pocket.

Over 6000 of these little Memo and Data Books have so far this year been distributed to manufacturing plant men in the following positions:

PRESIDENTS	SUPERINTENDENTS	MANAGERS	MINING ENGINEERS
VICE-PRESIDENTS	PURCHASING AGENTS	ELECTRICAL ENGINEERS	AUTOMOBILE ENGINEERS
SECRETARIES	MASTER MECHANICS	MECHANICAL ENGINEERS	

In other words, we have given the book without charge or obligation of any kind to those to whom the data would be of value and who hold positions of authority as regards the purchase of equipment.

Only about 500 of the books are still available, and if you desire a copy we suggest filling out the coupon below and forwarding it to-day—to-morrow may be too late.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways. W. C. McGHIE, Chairman of Board.
W. A. RIDDELL, M. A., PH. D., Superintendent, Trades & Labour Branch.

PLIBRICO — Endorsed by some of the leading Engineers as the GREATEST FURNACE LINING OF RECENT TIMES.

PLIBRICO—makes a solid one-piece lining without joints. Absolutely gas and air-tight. Saves its cost in fuel in a month or two—you will have a steady fire with less effort and less coal by using it.
PLIBRICO—is mixed ready for use, requires only half the time to install and does not require skilled labor. Any laborer who is at all familiar with the building line can use it. DOES NOT BREAK, CRACK OR SHELL OFF LIKE ORDINARY BRICK.
Can be used for front door arches, side walls, brick walls, combustion chamber and rear arches. Sets quickly—after a few hours with a low fire to drain out the moisture, you may fire up as usual. No special forms required.
Ideal for temporary repairs. Better order a barrel and have it ready for an emergency.

PLIBRICO BOND— A HIGH TEMPERATURE CEMENT FOR REPAIRS.

"PLIBRICO BOND" is a product which gives a perfect bond between fire-brick, and does not allow the fire to burn out the joints, as is the case where fire-clay is used. Prevents furnace walls from cracking and crumbling.
It's the most practical and logical high temperature mortar you can use. It's the ever-ready repair cement that you should have in case of emergency.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.
Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.
Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.
In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID,
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER

Record of CO_2 and stack temperature on one chart.

CO_2 Indicator for Boiler Front

Does your fireman know how much fuel he is wasting? Do you know?

The Uehling CO_2 Recorder makes a complete 24 hr. record of your combustion efficiency and the CO_2 indicator at the Boiler Front holds the fireman responsible.

Get more Steam per pound of Coal and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Uehling Instrument Company

2008 Empire Building New York City

Tycos Temperature Instruments

Indicating Recording Controlling

To meet the requirements of those innumerable processes requiring exact indication, measurement and regulation of temperature, we have developed *the most practicable and reliable* instruments that can be found.

H&M Type Angle and Straight Stem Thermometers

Recording and Indicating Thermometers

Automatic Temperature and Pressure Regulators

Mercury Vacuum and Absolute Pressure Guages

Engraved Stem Thermometers

Hygrometers, Hydrometers

Thermo-Electric and Radiation Pyrometers

Other Heat Measuring Instruments

Our more than fifty years of experience as makers of high grade, accurate instruments assures you that the *Tycos* products are as *different* from ordinary instruments as unusual skill, great care and the highest standard of manufacture can make them.

Let us work with you to secure the results you should have. Over half a century of TYCOS experience will thus be at your disposal.

Some day you'll wish you had—why not do it now?

Why not install now a positive prevention of the dangers arising from high and low water? One slip, one neglect in the old hand-regulated method may result in the destruction of thousands of dollars' worth of property—perhaps death.

Eliminate all chance of such an occurrence—install the Vigilant Feed Water Regulator. It will put a positive stop to all high and low water troubles. It is guaranteed to keep water level within ¼" of middle gauge.

And such cheap insurance! The Vigilant effects a saving in coal of from 3 to 17%.

Write to-day for interesting data, cards and complete Vigilant catalog.

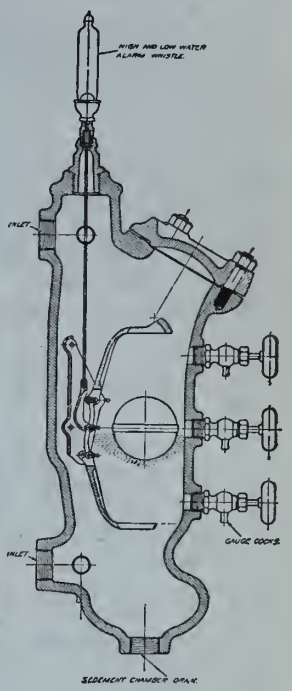
UNITY BUILDING - MONTREAL

Manufacturers in Canada of "S. & C." High Potential Fuses,—to 150,000 Volts.

SAFETY CERTAIN

With High and Low Water Alarms

Exterior



Cross Section

The "Anderson" Safety Water Column

Safety first, safety last, safety certain all the time—that's the assurance that you get from the "ANDERSON."

Water in your boiler cannot rise above or fall below the danger mark without the WARNING WHISTLE OF THE "ANDERSON" giving the alarm.

POSITIVELY RELIABLE—Working parts cannot rust or stick.

Write for full details.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

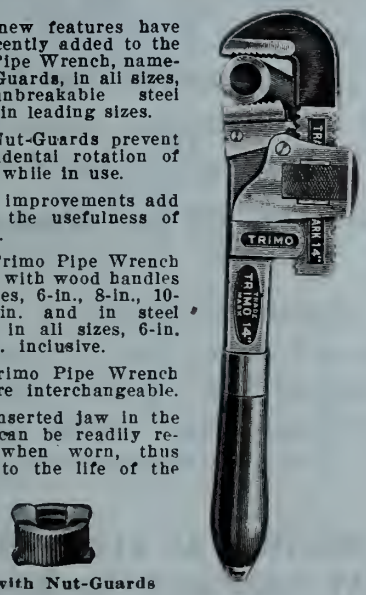
The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.



Nut with Nut-Guards

Inquiries from Importers and Dealers Solicited. Send for Catalogue No. 55.

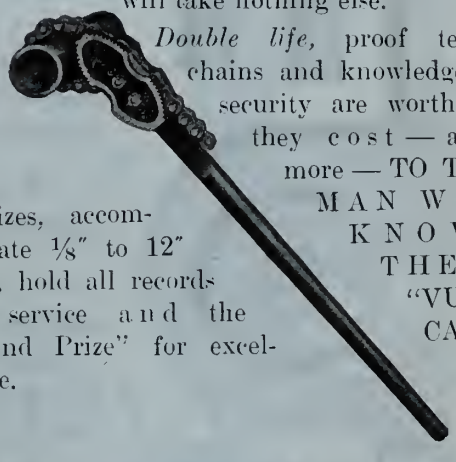
Vulcan-ize Pipe Work

Only the penny wise begrudge the price of "VULCAN" sufficiency. Experienced buyers will take nothing else.

Double life, proof tested chains and knowledge of security are worth all they cost — and more — TO THE MAN WHO KNOWS THE "VULCAN."



7 sizes, accommodate 1/8" to 12" pipe, hold all records for service and the "Grand Prize" for excellence.

STARRETT HIGH SPEED INDICATOR No. 104, Value $1.00 Given for two yearly paid-up subscriptions.

You May Have This Speed Indicator without Spending a Cent

if you are a subscriber to "THE POWER HOUSE." If you are not a subscriber, send in your own subscription together with two others, and the indicator you are entitled to will be mailed to you immediately.

To subscribers who send us two NEW yearly paid-up subscriptions we will send this $1.00 indicator.

"THE POWER HOUSE" is designed to give Canadian Engineers, Superintendents and Power Users all the latest and best information in the engineering field. A little work among your engineer friends and acquaintances will earn for you this handy indicator without any trouble. Try it and see how easy it will be.

PUBLISHED MONTHLY AT $1.00 PER YEAR

Banish Blow-off Troubles for All Time

A cost-saving proposition for the boiler room made possible by a recent achievement of the Homestead Valve Manufacturing Company.

A Winning Combination

THE
"HOVALCO"
RENEWABLE BLOW-OFF VALVE
and the
"HOMESTEAD"
QUARTER-TURN VALVE

Leak-proof it saves heat, which in turn saves fuel. Doesn't clog. Simple in construction. Made to withstand the strain of severe service. Write for full details.

Homestead Valve Mfg. Co., HOMESTEAD, PA.

If any advertisement interests you, tear it out now and place with letters to be answered.

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

INGLIS BOILERS

The boiler is of such vital importance in every plant that no firm thinks of installing one without a rigid investigation of the requirements and make. There's no requirement and no inspection that INGLIS BOILERS cannot meet successfully. For over fifty years INGLIS BOILERS have stood up against all tests with colors flying. Recommended by experienced Engineers in every part of Canada.

Inglis Boilers give lifetime service. Put your boiler problems in our hands. Write for numerous installations of various types, prices and specifications. Our representative will be pleased to call on you.

We are also sole Canadian makers of Erie City Water Tube Boilers, Vertical and Horizontal.

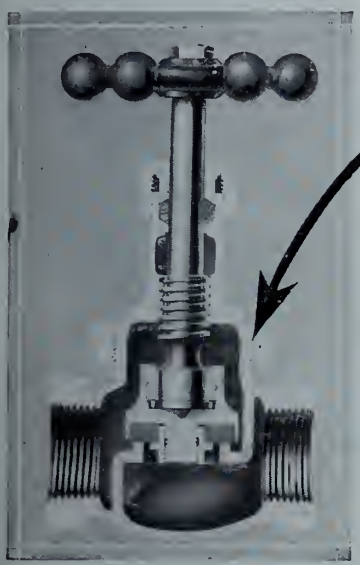
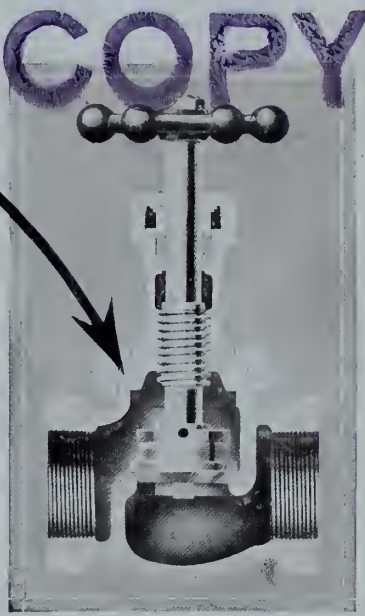
ALL PENBERTHY VALVES HAVE THE EXTERNAL THREAD CONSTRUCTION





COMPODISK

FOR

175 lbs. Steam Pressure

The Discs used in these valves will not crack or flake under high steam pressures or severe conditions.

Thousands in use giving the best of satisfaction.

MADE IN CANADA

The ARROWS Show You

That this Modern Improvement in Valve Construction Means to the Engineer.

STRENGTH and SAFETY

When you tighten down the bonnet of a Penberthy Valve there is **no danger** of spreading or enlarging the bonnet end of valve body which causes a loose fitting and unsafe bonnet **because** the Penberthy bonnet fastens to the body by outside threads. It's a union connection so to speak. These threads being **away** from corrosive action of steam and water are always clean, and the body and bonnet do not "freeze" together. A Penberthy Valve is therefore easy to take apart without strain or injury.

You will never know all the valve comforts until you have installed "the Penberthy."

REGRINDING

FOR

200 lbs. Steam Pressure

Some of the largest plants in Canada where this type of valve is preferred use Penberthy Regrinding Valves exclusively.

They are made in Globe Angle, Cross and Horizontal Angle, Vertical and Swing Checks.

RAINBOW

Over 50,000 engineers regularly specify RAINBOW, because it will make a tight joint that lasts for years.

RAINBOW has been used on every conceivable service in every industry. It's been tested so thoroughly that it is recognized as the standard sheet packing.

RAINBOW fits between the flanges like a mould. It is made of a compound that can't "burn" or "blow-out."

Start to use it to-day--you'll be more than satisfied.

McEWEN HIGH-SPEED AUTOMATIC ENGINES

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country is specially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

WATEROUS RETURN TUBULAR BOILERS

In both Stationary and Portable types, Waterous Return Tubular Boilers are specially suitable for every industrial use. They combine economy in fuel consumption, ease and convenience in operation, with absolute trustworthiness.

"Safety First" is not new as applied to these Boilers—it has been the idea behind every detail of their design and construction for fifty years and more. Exceptional care—exceeding the requirements of ordinary Provincial boiler building regulations—has been consistently exercised in the selection of materials and in every operation of their building.

Let the next boiler you buy be a "WATEROUS."

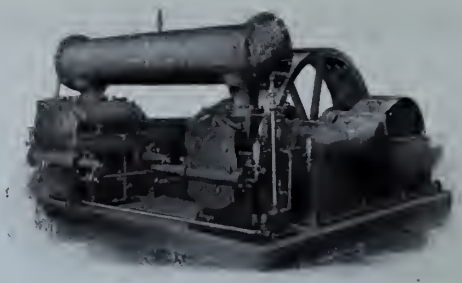
Jenckes Class CB-1 Air Compressor

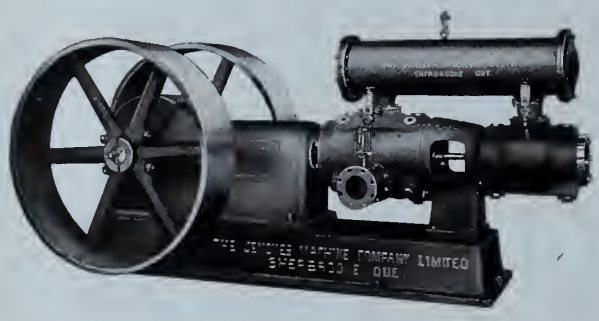
Single Stage



Jenckes Class DB-2 Air Compressor

Inlet valves are of the Corliss type, the outlet valves of the disc type. Lubrication is of the flood type, that is a continuous flood of oil is flowing over the bearings, crank pins, etc., all the time when the machine is in operation. Machine enclosed.

Write for full particulars.



Jenckes Class CB-2 Air Compressor

Two Stage

Our CB-1 and CB-2 compressors are equipped with disc inlet and outlet valves, which gives them long life and high efficiency, and makes them noiseless running. The machines are entirely enclosed. Lubricating system is of the splash gravity type, and the bearings are extra large.

JENCKES AIR COMPRESSORS

The design and construction throughout are of the highest class, the machines being built to successfully stand severe and continuous service. A Jenckes compressor is a paying investment. Write for full descriptive matter.

SPEED UP!

BURN THAT COAL no matter how poor. Get every bit of heat out of it and make your boilers develop their maximum capacity.

25 to 100% ABOVE RATING

This is easy when your boilers are equipped with

COPPUS TURBO BLOWERS

As one of our customers said the other day: "We got your blower going and now we are burning dirt." POOR DRAFT? Forget about it. Coppus Turbo Blowers take care of that also.

Perhaps the best proof of the SERVICE that we have rendered to the industrial world is our remarkable growth. Growth is inevitable when a concern provides an article of SERVICE. From a small beginning five years ago our manufacturing activities have expanded until to-day we are occupying the plant illustrated below.

We are to-day the largest manufacturers of Turbo Blowers in the world and without question build twice as many blowers as all the other manufacturers combined, among our customers being concerns who have as many as 150 to 200 blowers in their individual plants—certainly the best proof of satisfactory performance.

We take a natural pride and pleasure in calling attention to the new home of the Coppus Turbo Blower. Occupying nearly an acre of land we have provided for future expansion. 30,000 sq. ft. of floor space is utilized by our manufacturing department, testing laboratory, engineering department, and general offices, while, in keeping with modern practice, suitable quarters have been set aside for the welfare of our employees.

Here we will continue our policy of building integrity into our product. This has won success for us and satisfaction for our customers. We propose to hold our present patronage and add to it by a continuance of this same policy.

SEND FOR OUR CATALOGUE.

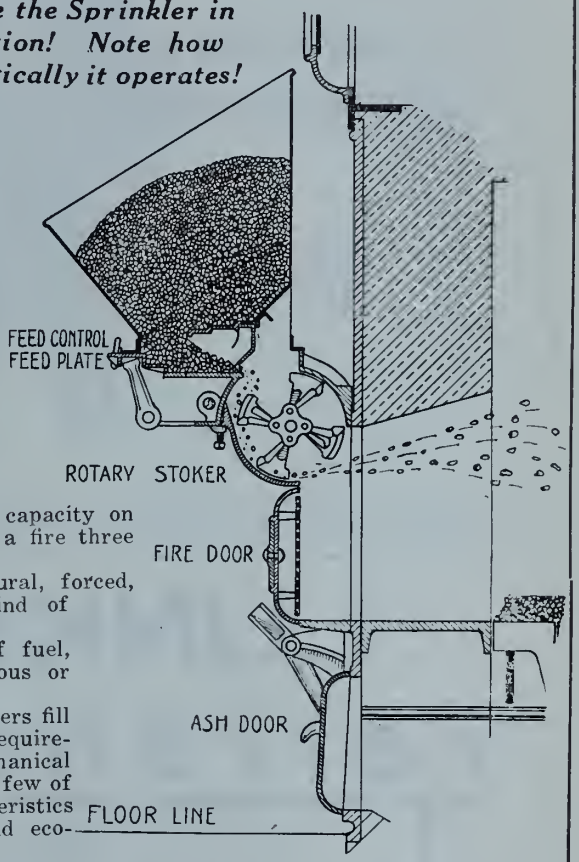
Two Type "A" Galt Sprinkler Stokers applied to 150 H.P. Return Tubular Boiler. (Coal Hoppers immediately removable.)

GALT SPRINKLER STOKERS

See the Sprinkler in action! Note how logically it operates!

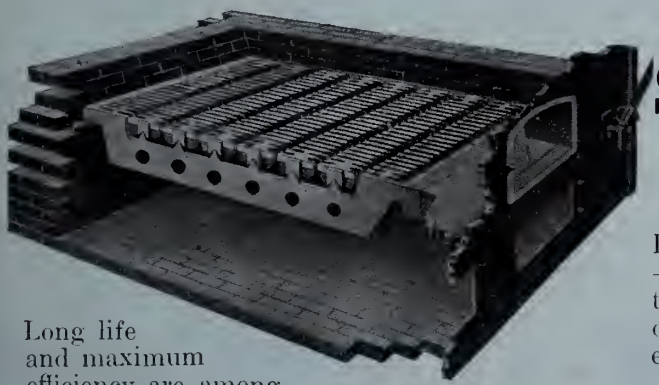


The Stoker mechanically feeds and perfectly spreads the fuel over the entire length and width of your present grates with the fire doors closed.

1. **Effects a saving in coal from 10% to 20%.**
2. **Effects a saving in labor from 25% to 50%.**
3. **Gives a brilliant, thin, perfectly level fire.**
4. **Gives smokeless combustion.**
5. **Increases the boiler capacity.**
6. **Increases the percentage of the CO.**
7. **Burns the fuel completely to the finest ash.**
8. **Operates for years without need of repair.**

Gives 170% boiler capacity on natural draft with a fire three inches thick.
Operates with natural, forced, induced or any kind of draft.
Burns any kind of fuel, anthracite, bituminous or lignite.
Galt Sprinkler Stokers fill every practical requirement of a mechanical stoker. Here are a few of the many characteristics of this efficient and economical appliance.

We supply Power-Turbo Blowers, McNaughton Rocking Grates, Damper Regulators and other Power Plant Equipment. Send for illustrated catalog.



Long life and maximum efficiency are among the outstanding features of the McNaughton Sectional Rocking Grate Bar.

McNAUGHTON
Sectional Rocking Grate Bar

Over 1200 in use in the Power Plants of the Country

Every user of this cost-cutting fixture is a booster for it—they all find it a success beyond their greatest expectations. It insures complete combustion of every pound of coal. Only ashes slip through the grate and this is effected by rocking—there's no waste.

Simple and durable in construction. Adaptable to all types of boilers and fuels.

LUNKENHEIMER
"Ferrenewo" Valves

The "Ferrenewo" embodies many exclusive features of construction, which not only give the greatest strength, but also increase the wearing life of the various parts, and consequently the valve as a whole.

The "Ferrenewo" is one of several Lunkenheimer Valves provided with the Lunkenheimer "Seat-guard," an annular extension on the bottom of the disc, which materially aids in preserving the seating surfaces and keeping them clean.

The "Ferrenewo" has a nickel Seatring and Disc, which, together with all other parts, are easily renewable.

The union bonnet, shoulder on stem for repacking under pressure, deep stuffing box with gland, etc., are other details which contribute to the efficiency of the valve.

Specify Lunkenheimer "Ferrenewo" and insist on having the genuine.

Your local dealer can supply you; if not, write us.

Installation Shows Two 600 H.P.

ROBB
Water Tube Boilers

Designed for 200 lbs. working pressure, installed in the power plant of the Goodyear Tire & Rubber Company of Canada, Limited, New Toronto, Ontario. Each boiler consists of longitudinal drums with flanged headers, and seamless steel tubes.

WE also manufacture Water Tube Boilers with Cross Drums, and have supplied 3,600 H.P. to the Dominion Government for the Lauzon Dry Dock near Levis, Quebec; 4,000 H.P. to the Aetna Explosives Company at Drummondville, Quebec, and approximately 2,400 H.P. to the Spanish River Pulp & Paper Mills, Limited, for their plants at Sturgeon Falls and Espanola.

WE build Horizontal Return Tubular Boilers, and have Installed Continental Scotch Marine Boilers at the instance of the City of Toronto in the new Filtration Plant on the Island.

THE ROBB-ARMSTRONG Vertical and Horizontal Steam Engines as prime movers for electric light and power purposes have been standard in Canada, Australia, and the countries of Europe for many years. Numerous successful installations might be mentioned, including Head Office Building of the Bank of Toronto, Canadian Pacific Railway Building, Traders Bank Building, T. Eaton Company, Limited; Robert Simpson Company, Limited; Nova Scotia Steel & Coal Company, Sydney Mines, N.S.; Canadian Pacific Railway Elevators, Fort William, Ontario; Perth, West Australia; Cleethorpes, England; Barcelona, Spain; Sao Paulo; Manchester, England.

WE have just completed the following installations of Rolling Mill Engines: Dominion Iron and Steel Company, one roughing engine 36" x 48", main bearing 21" x 33", and crank pin 15" x 12". Also one pair of 24" x 48" finishing engines. Fitted with piston valves. The Canadian Car & Foundry Company, one 42" x 48" Engine fitted with Corliss valves. Star Manufacturing Company, Dartmouth, N.S., one 22" x 24" Corliss type engine.

We are at present building a pair of 25' x 36" centre crank engines for the Armstrong, Whitworth Company of Canada.

If you will investigate our product you will find that it ranks first for design and service.

Mention this paper when writing advertisers. It will identify the proposition about which you require information.

Just a Ball—that's all

Two fundamental laws of physics vouch for the Johns-Manville Steam Trap

IF you believe that steam under pressure exerts its pressure in every direction and that a floating body rises and falls with the rise and fall of the water level regardless of water depth—then you'll believe in the Johns-Manville Steam Trap, for these unchanging laws control it.

There's just one moving part—the hollow ball—and it's operated solely by these two forces: Pressure, which holds it against the discharge orifice—the only point where there's an unbalanced pressure—and Buoyancy, which supplies the lifting force as the water level rises. So when condensate accumulates, the ball rolls up and exposes the discharge; when the water level falls, the ball rolls down and seals it. Positive in action, no air-binding, no steam-leakage.

The sureness of operation and the simplicity of the Johns-Manville Steam Trap mean freedom from trap troubles—and this isn't theory but fact, as hundreds of installations show. You can prove it for yourself at small cost by trying one out.

We Analyze the Water Before Preparing Treatment

Dearborn Feed Water Treatment is based on Knowledge—not Guesswork

Dearborn Treatment is based upon expert, scientific analysis of a sample of the boiler feed water you are using. The analysis, tests and compounding of the correct remedy are conducted in the largest, most modern, and thoroughly equipped laboratories and manufacturing plant devoted to the science of water treatment in existence.

In our twenty-five years' experience we have analyzed and treated waters of all classes, in many countries and under widely varying mechanical conditions. The knowledge and experience gained from this broad handling of the subject are brought to bear in the consideration of new propositions, to the direct advantage of the customer.

Dearborn Feed Water Treatment is made to suit the actual water conditions shown by analysis of the water used. It is not a "cure-all." It counteracts the elements that cause scale, pitting, corrosion or other troubles chargeable to bad feed water.

Send us a gallon of your feed water; we will send you a report of analysis and tell you exactly how much Dearborn Treatment prepared specially for your case will cost.

Nonpareil Cork Covering installed 11 years ago.
Sinton Hotel, Cincinnati, O.

Still Good After 11 Years

Back in 1905 the brine lines shown in the illustration were insulated with Nonpareil Cork Covering. Since that time—for over eleven years—the Nonpareil Cork has been keeping the cold in and the heat out, day after day. And it is still good for a long period of service.

That's the big advantage in using Nonpareil Cork Covering for Cold Pipes.

Not only is Nonpareil Cork a more efficient covering at the start, but it retains this efficiency and does not require costly repairs and replacements. Usually a coat of asphaltic paint every twelve months is sufficient to keep it in first-class condition.

The reason? Nonpareil Cork Coverning does not absorb moisture from the air by capillary attraction. It is made of nothing but cork.

Samples, prices and full information on request.

Nonpareil Cork Covering

LINDE

The Standard Refrigerating Machine

THE selection of Refrigerating Equipment for your business is essential to proper efficiency and economy. The selection of the particular type of machine you will use involves the same serious consideration as the selection of any other feature of equipment in your business.

Among others, Linde machines show indisputable constructional advantages combining the accepted features of design which are common, with certain individual features adding to strength, excess load carrying capacity, operating economy and availability for this particular work. Each type presents highly individualized construction adapting it in the fullest degree to the work it is called upon to do.

Twenty-one years of manufacturing prestige with a constantly increasing volume of business, and a record of re-sales to satisfied owners are your guarantee of satisfaction.

The Linde Canadian Refrigeration Co., Limited

37 St. Peter St., Montreal

Established and Manufacturing in Canada since 1896

A WINNER

During the past year hundreds of our enclosed type machines have been sold and are operating to the entire satisfaction of our customers. They are properly designed, and nothing but the best material and skilled workmanship used throughout, the same as has been our practice for over thirty-five years in the construction of our larger size vertical and horizontal types.

May we figure on your next installation, regardless of size or type, without obligation to you.

Write us any time and any place.

The VILTER MANUFACTURING CO.

Manufacturers of

ICE MAKING and REFRIGERATING MACHINERY, CORLISS and POPPET VALVE ENGINES, ETC.

242 Beecher Street, Milwaukee, Wisconsin, U.S.A.

Branch Offices:

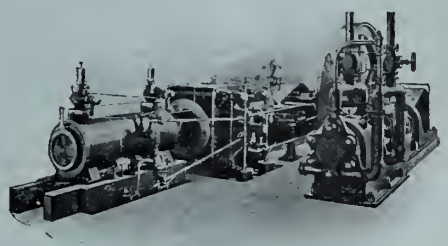
New York, N.Y.	Philadelphia, Pa.
Pittsburgh, Pa.	Chicago, Ill.
St. Louis, Mo.	Kansas City, Mo.
Houston, Texas.	Los Angeles, Cal.
Salt Lake City, Utah.	Seattle, Wash.
Wellington, New Zealand.	

Products

Vilter Rolling Mill and Girder Corliss Engines, Poppet Valve Engines, Ice Making and Refrigerating Machinery, "Badger" Pasteurizers for Pasteurizing Milk or Beer In-The-Bottle. Machinery for Breweries and Bottlers, etc.

Vilter Improved Poppet Valve Steam Engine

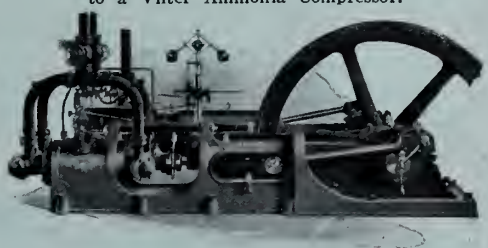
Vilter Poppet Valve Engines effect real power plant economy. We know our statement will be attested to by owners and operating engineers of the plants where Vilter Poppet Valve Engines have been installed. Your request for proof need entail no obligations to purchase.



Vilter Tandem Poppet Valve Engine, direct connected to a Vilter Ammonia Compressor.

Vilter Rolling Mill Type Ammonia Compressor

The Rolling Mill Type Compressor is built along very heavy lines and for all conditions of service. It is used only with slight modifications in all sizes of compressors. The general design is very pleasing to the eye, the machine making an artistic asset to any engine-room. Its very appearance gives assurance and proof of its strength and reliability. This type is built in sizes from 6 Tons to 25 Tons daily refrigerating capacity.



Rolling Mill Type Compressor.

Vilter Duplex Heavy Duty Ammonia Compressors

A Duplex steam-driven unit, with horizontal double-acting ammonia compressors and direct connected to Cross Compound Corliss Engine. Compressor equipped with multiple valve heads, giving maximum area. Stuffing box of the double-packed type, with oil seal and pressure release. The duplex type is built in sizes from 125 to 750 tons.

Vilter Small Capacity Vertical Ammonia Compressor

A vertical single-acting compressor, specially designed for users of comparatively small quantities of refrigeration. Made in both single and twin cylinder units. The single units, either belt or steam driven, are made in sizes from 1 ton to 12 tons daily refrigerating capacity. The twin cylinder units, belt driven only, are made in sizes from 2 tons to 25 tons daily refrigerating capacity.

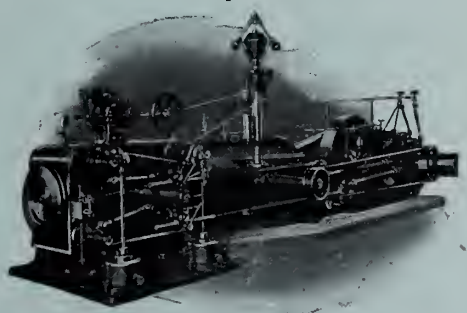
Vertical Ammonia Compressor.

Vilter Rolling Mill Type Corliss Engine

The Rolling Mill type Corliss Engine is of exceptionally massive construction throughout, and is adapted to any class of service from the steady belted load to the direct connected electrical service, in which the engine is subjected to heavy and extremely variable loads. It is built for high steam pressures and high rotative speeds, and may be used with superheated steam up to 100° F. superheat.

Vilter Girder Frame Corliss Engine

is exceedingly strong and rigid, and is designed to take shocks and overloads without possibility of misalignment. Made in 26 sizes, from 25 h.p. up.



Rolling Mill Type Corliss Engine.

LITERATURE. Bulletins, catalogues and full data regarding our products will be mailed upon request.

The Finest Ice-Making Plant In Canada

THE illustrations show equipment designed, furnished and installed by us in the Dupont Street Plant of the Lake Simcoe Ice Supply Co., Limited, Toronto.

Although the plant is only rated at 75 tons capacity per 24 hours, when pushed it has turned out 20% more ice than this amount. It is of the very latest design, embodying all features known at the present time for producing ice of the best quality most efficiently.

It will pay you to consult us regarding your requirements in this line.

JONES

UNDERFEED AUTOMATIC STOKER

Eliminates Smoke and Makes More Steam With Less Coal

It is a well-established fact among steam users now that the mechanical method of firing is cheaper and more efficient by far than the old hand method of firing.

You get more steam from less coal—and furthermore all smoke nuisances are banished.

Since it is generally conceded that mechanical methods of stoking are best, it is then a question with you, which is the best of the mechanical methods. Your attention is directed to the **Jones Underfeed Automatic Stoker.**

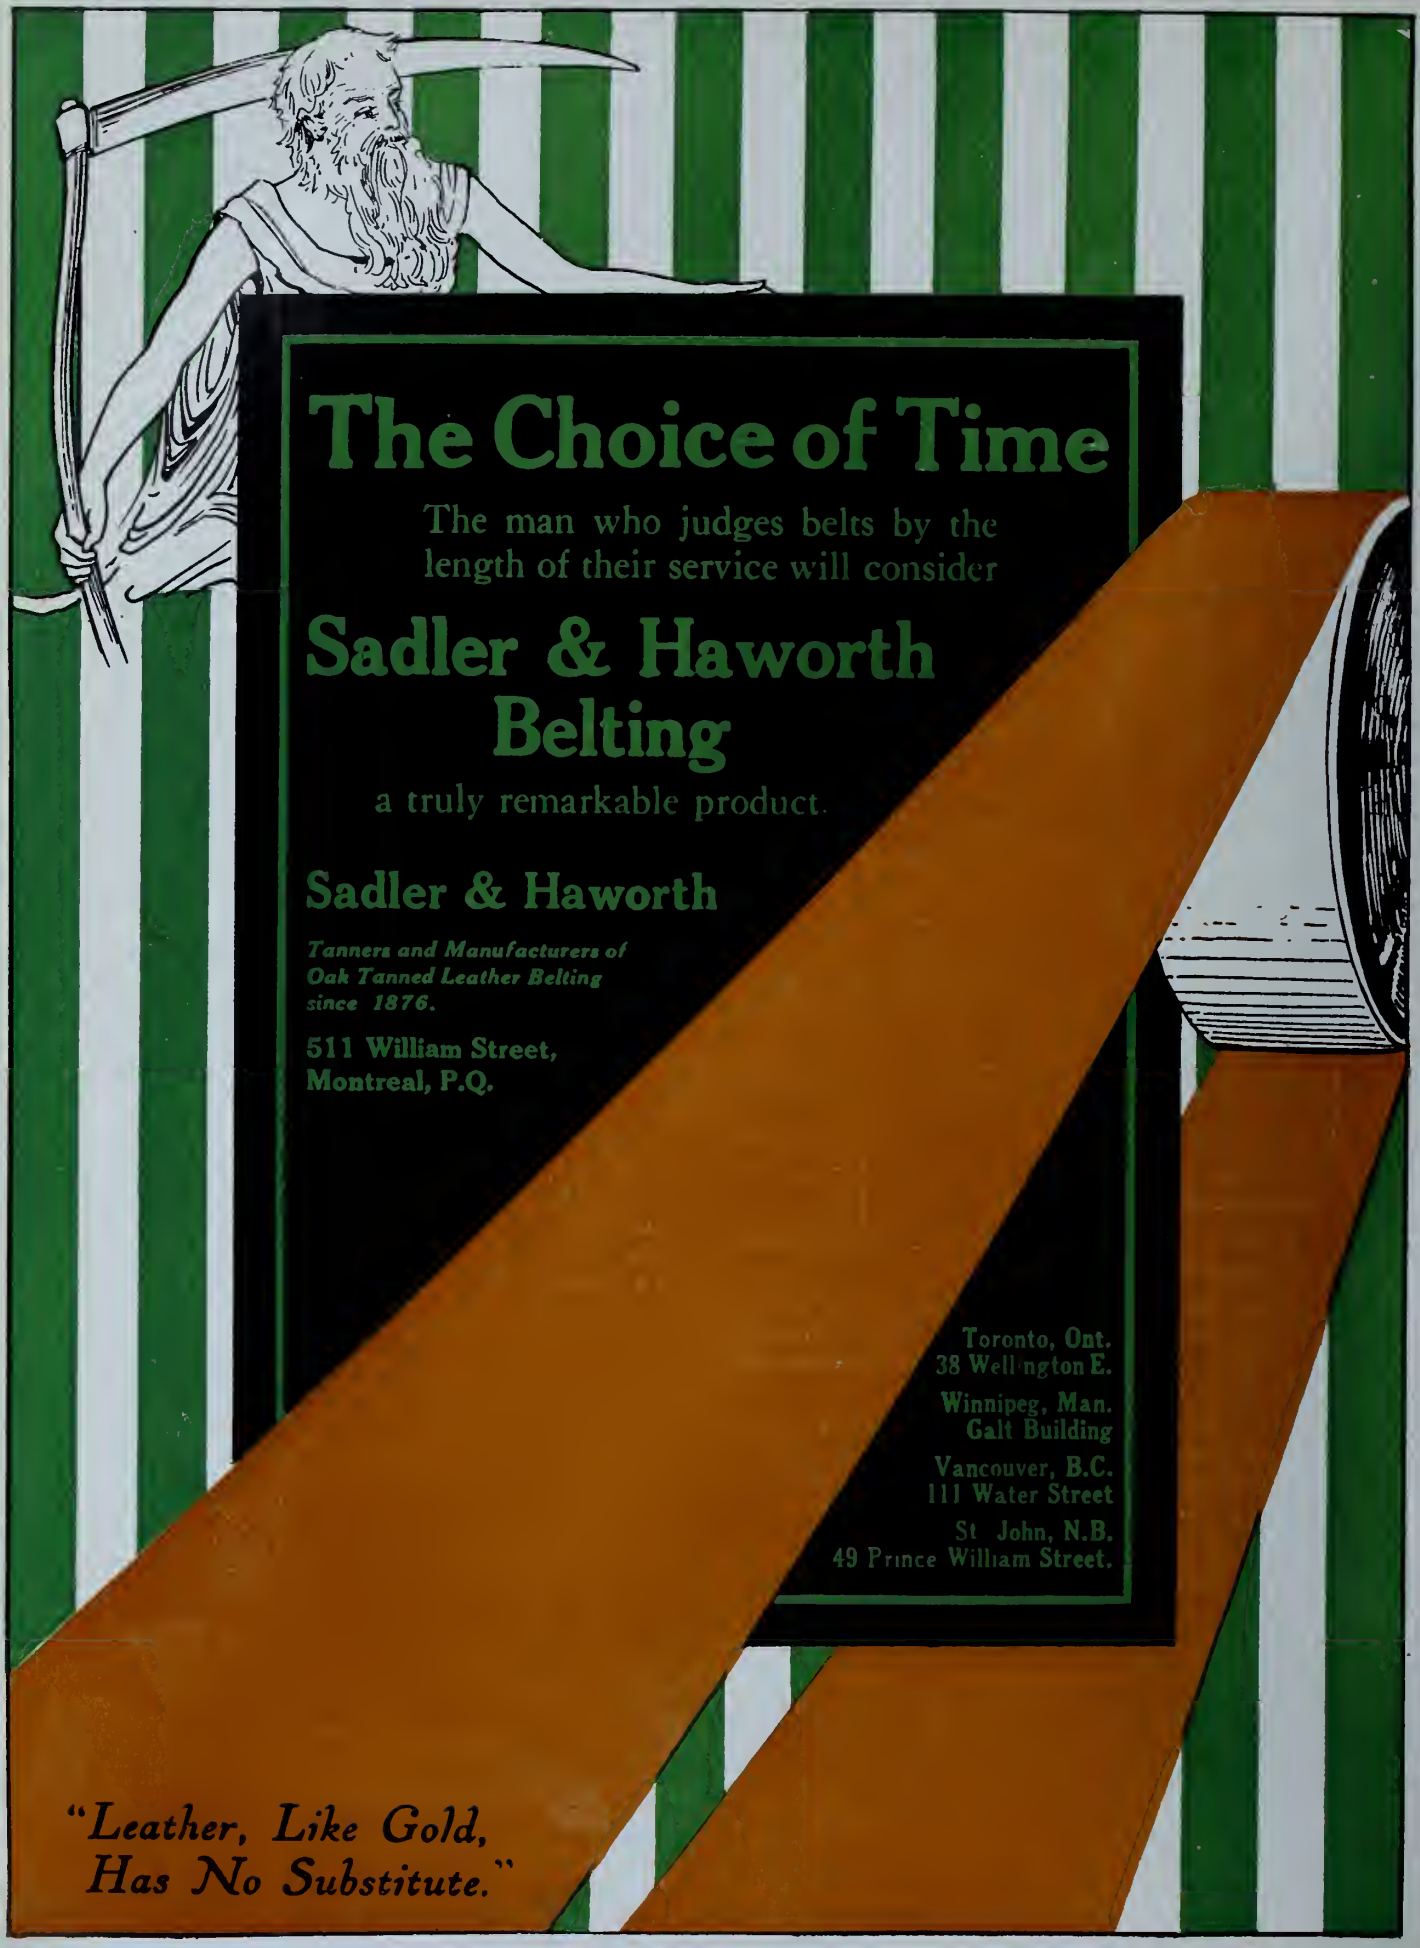
The Jones Stoker maintains a constant steam pressure because of the automatic control of air supply and coal supply. It increases boiler horse-power developed by its unlimited capacity to feed coal and simultaneously introduces extra air required in proper proportion for combustion. Immediately responds to fluctuating loads and sudden demands for steam. No soot! No smoke! Burns any kind of coal! Let us tell you the reason why.

There are a lot of interesting things to tell about the Jones Stoker. Give us your address.

Jones Underfeed Stoker Company, Limited

37-41 BRITAIN ST. TORONTO

The "Jones" embodies the most practical features of mechanical stoking known to science. Underfeed stoking is the only device for burning coal which utilizes as fuel all volatile ingredients. So there is no waste with the **Jones Underfeed** Stoker in action—everything that should be burned to generate steam is consumed.



The Choice of Time
The man who judges belts by the length of their service will consider
Sadler & Haworth Belting
a truly remarkable product.

LEATHER BELTING

TRADE MARK

More for Your Money

D. K. McLAREN'S BELTING has "made good" in so many instances that it is pretty safe to say that it gives you more for your money than the belting you are now using.

If you are noticeably losing time through slippage and breakage it is not probable, but CERTAIN, that D. K. McLAREN'S BELTING will give you more for your money; for this **GENUINE BRITISH OAK-TANNED PRODUCT** gives all the efficiency within the range of possibility, or, in other words, all belts must slip a little and break sooner or later, BUT McLaren's is a minimum slipper and a minimum breaker.

Our time-tested British Oak tanning process assures strength, durability and pliability to all our belts.

Let us put you in touch with some users of our belts. Write to-day.

FOR HIGH SPEED ENGINES

Encanto, Calif.,
March 3, 1916.

Magnolia Metal Co.,
Gentlemen:—

You may use this letter for publication, if the same will in any way help to further your best interest.

Your metal has given me the best satisfactory results in high speed engines.

I have used this metal for main bearings and crossheads, it has stood up under all conditions and I never have found MAGNOLIA METAL anything but what you have represented it to be.

Very respectfully yours,
J. L. WURTHMANN.

PRACTICAL ENGINEER POCKET BOOK:
Over 600 pages. A valuable reference work imported from England and sold as an advertising medium at the low price of 40c post paid.

The Bond Patent "Spiro"

The PRICE is never right if the quality is wrong. QUALITY in Power Transmission Equipment means correct design based on long experience and skill in manufacturing and finishing.

When you buy BOND Transmission machinery, you know the quality is right, for we have had twenty-five years' experience.

And at the same time BOND transmission equipment can be bought at prices as low as are now charged for many inferior lines.

Write to-day for our complete catalogue.

Canadian Bond Hanger & Coupling Co., Limited

Alexandria, Ontario

The Original Four-Point Hanger

"That belt must be slipping, George! It's too loose on the pulleys!"
"No it isn't, Uncle. If it slipped at all, it wouldn't stay on the pulleys a minute!"

THE new Superintendent was different. For the first few days he just walked through the plant and looked at things. Down in the engine room he took the speed of the engine. Up in the shop he took the speed of the main shaft. Then he did some figuring. These are the figures.

Driving pulley 8 feet diameter.
Speed 80 rev. per minute.
Driven pulley 4 feet diameter.
Speed should be 160 rev. per minute.
Speed actually.. 155 rev. per minute.
Loss ..... 5 rev. per minute.
5 ÷ 160 = 3% approximately.
8 ft. × 3.1416 × 80 rev. per minute = about 2,000 feet per minute the belt travels.
3% of 2,000 feet = 60 feet per minute LOST.
Pulley centres at 20 feet, so belt length approximately 60 feet.

This meant that once every minute his belt was useless, for the loss in feet per minute due to slipping was more than the length of the belt itself!

In a ten-hour day this loss would be 36,000 feet, so that every day the engine had to give that belt a free ride of nearly 7 miles! And the firm paid the bills at the coal pile and machines, at the bearings, pulleys and in the belt itself. It didn't look right.

The plant had over one hundred belts. If they all slipped, the firm must be losing hundreds of dollars a year in power, time and equipment which might better be saved.

* * * * *

The new Superintendent never did things on impulse, or merely on someone else's say-so. Back in his experience he had used CLING-SURFACE, the treatment which PREVENTS SLIPPING, and allows the usual drive to be run easy or slack under full load. He knew that it makes constant tension unnecessary, preserves and makes the belts thoroughly pliable and waterproof; that it is not sticky, contains no rosin or anything harmful, and is safe, easy and economical to use.

So he had every belt treated, and the effect was seen at once. His slipping stopped, he had more and steadier power, and not a belt has been taken up since that time.

This is fact; we can prove it on your drives to YOUR satisfaction. Just ask for THE PLAN 10,000 firms have found successful.

And remember, use CLING-SURFACE and you won't need belt dressings.

Morehead Back to Boiler SYSTEM

It is saving large percentages in fuel bills.

Giving satisfactory service under most difficult conditions

Saved 33% on fuel bills.

Montreal, Sept. 19, 1916.

Gentlemen,—Yours of the 14th inst. at hand. In reference to our Morehead Trap we cannot speak too highly of same; facts will prove more than literature; we really believe that it has saved us 33 per cent. on our fuel bills since we have had it.

We sincerely remain,
Yours truly,
(Sgd.) ROBIN FRERES.

The only system for them

London, Canada, Aug. 5th, 1916.

Dear Sirs,—In reply to yours of August 4th regarding the trapping system, which you installed for us, we are pleased to state that it has been perfectly satisfactory up to the present date and we would not return to our previous system under any consideration.

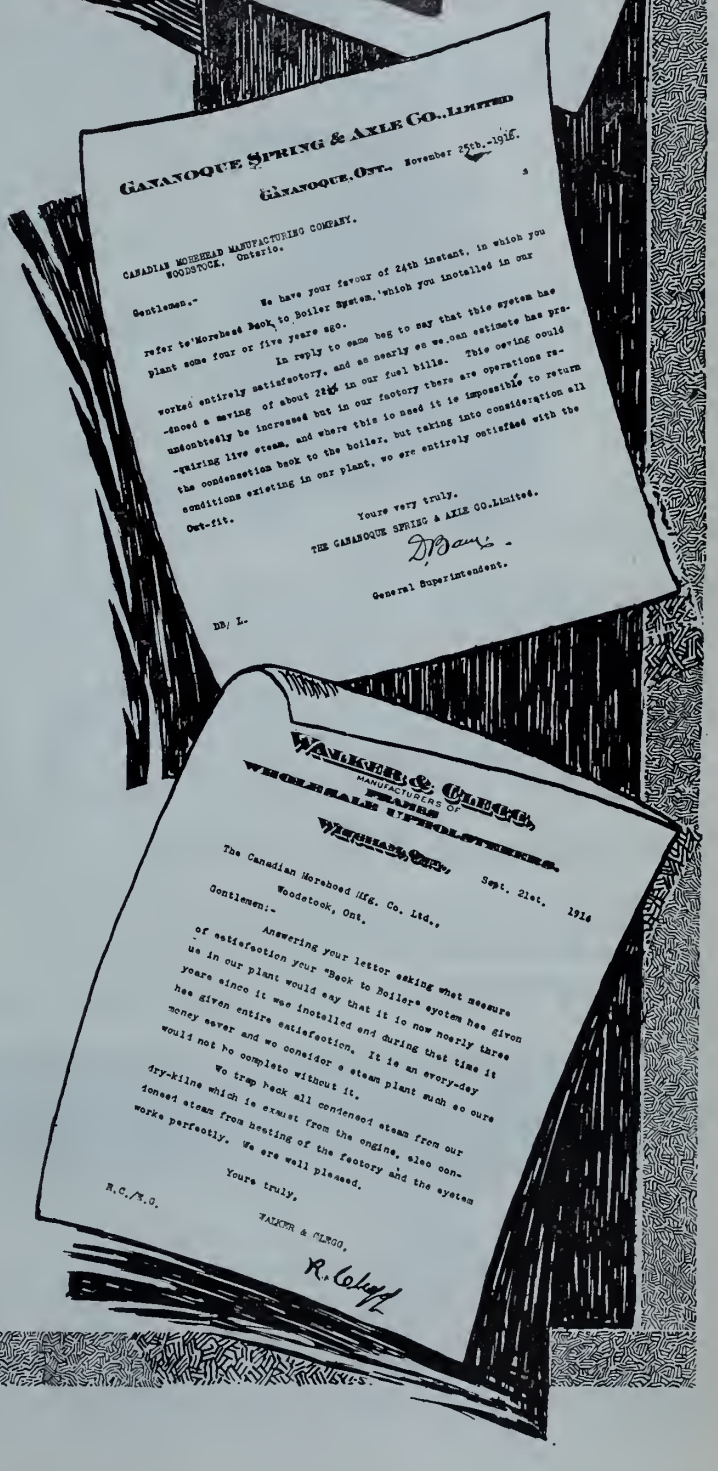
Yours truly,
(Sgd.) GORMAN ECKERT & CO., LTD.

Through a fire— still operating

Hamilton, Ont., September 14th, 1916.
Re Back to Boiler System.

Dear Sirs,—In reply to your favor of the 11th instant, we beg to state that since installing your Morehead Back to Boiler System we have had no complaint whatever from our engineer, although the Trap was in the midst of the hottest part of the fire we had recently in our factory. With the exception of renewing some packing the Trap has performed its duty to our satisfaction, necessitating no repairs whatever, excepting packing as stated.

Yours respectfully,
(Sgd.) LUMSDEN BROS.



GANANOQUE SPRING & AXLE CO., LIMITED

GANANOQUE, ONT., November 25th, 1915.

CANADIAN MOREHEAD MANUFACTURING COMPANY.
WOODSTOCK, Ontario.

Gentlemen.- We have your favour of 24th instant, in which you refer to Morehead Back to Boiler System, which you installed in our plant some four or five years ago.

In reply to same beg to say that this system has worked entirely satisfactory, and as nearly as we can estimate has produced a saving of about 22½ in our fuel bills. This saving could undoubtedly be increased but in our factory there are operations requiring live steam, and where this is used it is impossible to return the condensation back to the boiler, but taking into consideration all conditions existing in our plant, we are entirely satisfied with the Out-fit.

Yours very truly.
THE GANANOQUE SPRING & AXLE CO.Limited.

WALKER & CLEGG
MANUFACTURERS OF
WHOLESALE TYPEWRITERS
WINNIPEG, MAN., Sept. 21st, 1916

The Canadian Morehead Mfg. Co. Ltd.,
Woodstock, Ont.

Gentlemen:-

Answering your letter asking what measure of satisfaction your "Back to Boilers" system has given us in our plant would say that it is now nearly three years since it was installed and during that time it has given entire satisfaction. It is an every-day money saver and we consider a steam plant such as ours would not be complete without it.

We trap back all condensed steam from our dry-kilns which is exhaust from the engine, also condensed steam from heating of the factory and the system works perfectly. We are well pleased.

Yours truly,
WALKER & CLEGG,
R. Clegg

***RE* PROTECTO BOILER COMPOUND**

Gentlemen:—Before we used this material our Boiler had scales on it, in some places ¼" thick and although we have used PROTECTO for only about one month and a half, our Boiler now has a good deal less scale, and in our opinion, it will only be a matter of a short time until it will be entirely free from all scale.

It is now a noticeable difference in the amount of fuel which we consume, and we would not want to be without PROTECTO.

We are enclosing herewith a few samples of the scale which PROTECTO has removed from our Boilers, we think you will be interested in seeing this.

You may use our name as recommending PROTECTO for Boilers.

Yours very truly, ST. CATHARINES SILK MILLS LTD.

What Do Your Floors Cost?

WE don't ask what they are *worth*—we ask how much they cost you in lost time, cost of maintenance and damaged machinery.

—Perhaps it has never occurred to you that unprotected cement floors may be the cause of your machinery trouble. Perhaps you never realized that the fine, gritty dust from the floors is what makes your bearings run hot and your dynamos and motors to spark.

R.I.W. REMEMBER ITS WATERPROOF REG. U.S. PAT. OFF. CEMENT FILLER & CEMENT FLOOR PAINT PATENTED AS TO PORTLAND CEMENT FEB 27 1906

will make your floors durable, dustless and cheaper to maintain. Oil, water and acids cannot soak into and soften the cement because the surface is scientifically sealed.

Floors treated with R. I. W. Cement Filler and Cement Floor Paint will not crack or disintegrate and will give longer, cheaper and more satisfactory service all around.

They are specified by experts the world over.

Write for descriptive literature, Dept. 59.

re: DEAN CLEANER.
Gentlemen:
I wish to say that since using the DEAN, I have effected a great saving in fuel.
Previous to its use, I burned the best R.O.M. coal—now I burn screenings and only a little more than half the quantity, at the same time developing about 15 H.P. more than before.
I think that if the DEAN CLEANER was better known to engineers in Canada, they would not care to be without it. I would willingly demonstrate its good points to any engineer who might have any doubt about it—
BUT—I could not show results, as I have no scale on the boilers to come off.
Yours very truly,
Engineer.

—since using the DEAN I have effected a great saving in fuel

Every engineer knows that clean boiler tubes mean better steaming. But not every one can be convinced that if he keeps his tubes free from ALL scale, he can frequently, by experimenting use cheaper fuel—and still develop the same, or greater, horsepower.

Mr. Farrow used to burn the best run-of-mine coal. His employers thought the coal bills were too high It seemed that substantial economies could be effected. So, a Dean Boiler Tube Cleaner was installed on trial.

(See Mr. Farrow's letter above for statement of results).

We do not advance the argument that you can use the Dean Cleaner and equal Mr. Farrow's results. Possibly you have already solved this problem. But, we do believe that if you used the Dean, it would produce surprising results and be a valuable addition to your plant.

The great secret of the Dean Cleaner's success lies in the fact that it does not leave a particle of scale in the boiler, as so many other cleaners do, but removes it ALL, thus bringing into the most direct contact the heat and water.

A request for description of the Dean Cleaner will bring a prompt response, including details of free trial offer.

Our Rear Combustion Chamber Arch

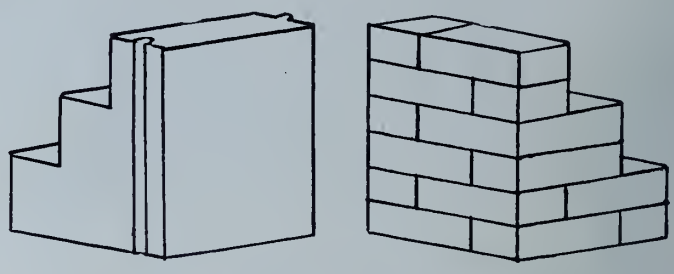
Gates Fire-Brick Blocks More Durable and More Efficient Than the Ordinary Fire Bricks

They form a much thicker wall around the fire, thus conserving the heat and reducing fuel bills. Number of joints in furnace wall open to attack of deteriorating influences greatly reduced, ensuring long life.

Air-Proof Firebox Lining

Clinkers do not readily form on their smooth and even surface, and the tongued and grooved joints prevent air leaks, making the firebox perfectly air-tight. Thus the lining not only lasts longer, but tends to promote better combustion. They can be readily removed and replaced without disturbing the surrounding brickwork, a feature not to be found in any other Block.

We manufacture: Boiler Door Arch Blocks, Boiler Door Jamb Blocks, Rear Combustion Chamber and Firebox Blocks. We also contract for and specialize in: Boiler Setting, Furnace Building, Oven Work, and all kinds of Power Plant Brick Work.



Three Chances to One in Favor of Gates

Add the number of inches of joints in the piece of brickwork at the right and compare with the number in our solid block at the left. The brickwork has more than three times as many. That means three times as many chances for the heat to attack the body of the brick and bring your firebox lining to a quick end. The material in our block is more durable than that found in ordinary firebrick.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseeu strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

Important Announcement

AS was intimated in our June issue, Graded Certificates will in the near future be in force in the Province of Ontario. Just how soon the regulations will go into effect is a matter that will be determined by the Government, but sooner or later Ontario engineers will be required to write their examinations.

Beginning in this issue of POWER HOUSE there will appear a series of Questions which engineers will have to answer. They are substantially the same as the questions which will be used in connection with the coming Graded Certificate Examinations. Their answers will be given in POWER HOUSE and any engineer who will study the series of Questions and Answers cannot fail to be greatly benefited.

And what is good for those who may have to try their examinations will also be found good for those who do not have to qualify and it will be found equally beneficial by those who have already qualified.

This number of POWER HOUSE, aside from the initial installment of the Questions and Answers Series, is well worth preserving. It is full of valuable information and deserves the careful study we feel sure it will receive.

Our Editor, Mr. Bain, has provided an exceptionally large and interesting bill of fare editorially while the advertising sections are most instructive, containing as they do the messages of many of the leading manufacturers of power equipment and supplies.

In anticipation of a heavy demand for our July issue we printed an extra supply and new subscribers may commence their subscriptions so as to receive this issue.

50 YEARS OF BUSINESS EXPANSION*

BY

W. A. CRAICK**

There is here given in racy fashion, yet evidencing in the variety detail discussed considerable painstaking and scrupulous regard for developments in the period under review, to the end that as far as possible everything embraced by the article title, wide in scope as it happens to be, should get at least a passing reference. Speaking generally, the advances made in the spheres of Industry, Finance, Transportation and Insurance are prominently featured.

CANADA'S position at the close of the fiftieth year of Confederation is imposing only in so far as present day conditions are placed in contrast with those prevailing at the dawn of the Confederation era. Progress is at best a relative term, and to appreciate to the full the extent of this country's development, one must visualize the setting in which that development was commenced.

To all intents and purposes, the whole of Western Canada, with its far-flung population, its many fine cities, its thousands of miles of railway and its enormous agricultural production, must be eliminated from the canvas. It is true that by 1867 some ten thousand people had settled in the Red River Valley; that stragglers had penetrated even farther west. It is also true that the gold rush of the late fifties had poured population into the Fraser River Valley and that Victoria was already a fair-sized town. But these widely-separated settlements, on the prairies and at the Coast, were almost as distant from Eastern Canada in those days as Australia is to-day, and further, their business associations were entirely with the neighboring sections of the United States.

Canada in 1867

The picture of Canada in 1867 narrows, therefore, to the comparatively restricted limits to the older settled portions of the country—the narrow fringe of clearing along the St. Lawrence; the lake front counties of Ontario; the coast and river settlements of New Brunswick and the scattered towns and fishing villages of Nova Scotia. The wider vision of a great and prosperous West had not yet seized upon the minds of the people and their field of possible endeavor lay no further off than the thickly wooded concessions of the back counties.

Though fairly well populated and supplied with the modern means of communication, the older sections of Quebec and Ontario were still in a comparatively crude and undeveloped condition. Even between Montreal and Toronto, then as now, the two foremost centres of population in Canada, the appearance of the country was anything but prepossessing. There remained much uncleared land. Many of the homes of the inhabitants were at best but miserable shanties. The people were poor; the children dirty and ragged; the cattle lean. Towns, which were quite as numerous as they are to-day, and in several cases nearly as large, were suffering from the after-effects of the Grand Trunk boom, and exhibited numerous unoccupied and delapidated buildings.

From Prescott to Ottawa, then the customary route to the Capital, the railway traversed what appeared to be a continuous pine swamp, wet, dismal and depressing. The Capital itself lay hidden away in the midst of green, unbroken forests, which closed in on the log houses and small villas lying on the outskirts of the embryo city.

To the rear of the counties fronting on the St. Lawrence and Lake Ontario, settlement was just getting under way at the time Confederation came into being. Railways were being promoted to tap the resources of Peterboro, Victoria, Simcoe, Grey and Bruce Counties, and settlers were arriving from the Old Country to people their solitudes. In fact, this particular section of Canada was going through an experience which has since been duplicated many times in the West.

The Government was devoting special attention to the settlement of the free grant lands in the Muskoka District. Advertising matter of the same brand as that which later lured thousands of immigrants to the prairies, told of the prospective wealth to be derived from the cutivation of the soil in this remote part of the province. In response to the appeal, population was penetrating as far north as Parry Sound on the shore of the Georgian Bay, while Bracebridge was thronged with newcomers.

Oil and Gold Booms

It was about this period, too, that the oil boom in Enniskillen Township and the gold boom at Madoc were absorbing public attention. The former attracted the curious from all parts of the country. To reach the oil fields, visitors had to leave the Sarnia branch of the Great Western at Wyoming and drive through the woods to Oil Springs. It was a trip, as described by travelers, full of spectacular interest. The great dark forest, traversed by a narrow plank road; the constant succession of carts coming and going with their barrels of oil; the derricks, oil tanks and engines scattered through the clearings, all presented a scene of strange and outlandish character. Oil Springs itself was a village of wooden hotels, thronged with speculators and hangers-on, who by their frenzied efforts to secure paying properties increased the popular interest in the district.

The Madoc gold finds were made in the year before Confederation and the rush to the mines in the spring of 1867 was one of the events of that momentous year. Prospectors in large numbers thronged to the new gold fields, from which so much was expected, and many miners, who had participated in the California and British Columbia rushes, made their way to the new Eldorado. Five lines of stages from Belleville to Madoc

*Also in MacLean's Magazine.
**Of MacLean Publishing Co. Staff.

were for a time insufficient to accommodate the crowd who sought access to the scene of the discovery.

These events, bulking largely in the popular imagination at the time, have long since dwindled into their proper proportions. The oil wells of Enniskillen have become a commonplace; the gold strikes at Madoc have sunk into insignificance. Reference has been made to them merely to illustrate how places which fifty years ago were on the very fringe of settlement and to reach which tedious journeys had to be made, are now left far in the rear by the tide of progress. The gold of Porcupine has long since eclipsed the gold of Madoc, and in Southern Alberta the oil prospector has been finding new fields for his investigations.

Lumbering

In various other respects conditions have changed in old Ontario and Quebec. Lumbering was a far more important industry fifty years ago than it is to-day. The Great Western Railway brought down from its Sarnia branch annually large quantities of oak timber. This wood was rafted at Hamilton and towed to Quebec for export to the Old Country. The Northern Railway carried to Toronto, and the Port Hope, Lindsay and Beaverton Railway hauled to Port Hope trainload after trainload of lumber for shipment by schooner across the lake. Cordwood was one of the commonest commodities of the day, and trainloads of it were a common sight on the railroads fifty years ago. It was used not only for heating and cooking, but it formed the universal fuel for locomotives, and from the back settlements thousands of cords were shipped annually to the United States.

LUMBERING ON THE UPPER OTTAWA. A FLOURISHING INDUSTRY AT THE TIME OF CONFEDERATION.

Early City Settlements

The extent of settlement in 1867 was reflected in the cities. To-day there are in the Dominion six cities with populations in excess of 100,000 — Montreal, Toronto, Winnipeg, Ottawa, Hamilton, and Quebec—while a seventh, Vancouver, falls little short of that figure. In the year of Confederation, however, Montreal was the only urban centre that came within 50,000 of reaching the 100,000 mark. Toronto could not boast 50,000 inhabitants. Winnipeg was a mere hamlet. Ottawa contained but 15,000 people. Hamilton just exceeded 20,000 by a narrow margin. As for those flourishing Western cities—Calgary, Edmonton, Regina, Saskatoon, Brandon, Moose Jaw, and Vancouver—they were practically all non-existent. Only conservative old burgs like Quebec, Halifax, and St. John, had populations in any way commensurable with present figures.

Our Capital City

The beautiful capital city of the Dominion, whose natural charms have been greatly enhanced by the work of the Ottawa Improvement Commission, has developed during the fifty years of Confederation from a crude backwoods settlement into one of the finest cities in America. So unprepossessing was its appearance when it was selected by Queen Victoria to be the seat of government, that it was described as the Cinderella of Canadian Cities. Its intrinsic beauty was recognized, but that beauty was so hidden by uncouth and dirty surroundings that the comparison was by no means inapt.

Curious visitors who went to view the new capital during the early sixties, came away with mixed impressions. It was admitted that the site of the Parliament Buildings was a lovely one; that the surrounding forests had a wild impressiveness, and that the clear air, everlasting resounding with the noise of falling water, was exhilarating, but what were these natural attractions when everyday living conditions were so bad? The streets were rough, the houses mean and squalid, the hotel accommodation wretched, and the food poor. Lumber and sawdust littered the place until it looked like one vast timber yard.

A sister of Lord Monck, who visited the town shortly before the Governor-General moved there from Quebec, groaned over the prospects of life in such a place, describing it as "t'other end of nowhere." And it is known that civil service employees, who had to forsake the comparative loveliness of Toronto, Montreal, or Quebec, for its early crudities, bemoaned their fate, while Ministers of the Crown took the earliest opportunity to escape from its impenetrable dullness.

Of course, all this has changed. Ottawa to-day boasts the possession of every modern facility, not only for the enjoyment, but for the improvement of life. Its beautiful streets and parks, its splendid public buildings, its superior hotels—all these combine to render the contrast with the miserable, down-at-the-heel settlement of fifty years ago most striking and complete.

And what of other cities? Montreal,

the foremost city of the Dominion with its more than 600,000 people could, in 1867, muster barely one-sixth of that number. In extent it was very considerably smaller. Its principal business thoroughfare of to-day, St. Catherine Street, lay on the outskirts of the city. Even lordly St. James Street, with its splendid financial institutions, was only just in course of construction. Business centred in Notre Dame Street; McGill College stood out in the suburbs, and it was a mile walk from the edge of the city to the mountain.

In several respects, Montreal, fifty years ago, was greatly inferior to the present city. Its streets were notoriously filthy, especially along the docks where the mud frequently lay knee-deep. The lighting even of the main thoroughfares was inadequate, gas being then the universal illuminant. The drainage was bad, and in this connection one visitor tells of having to leave the Theatre Royal one night in the middle of an amusing comedy on account of the vile odors that were wafted in through the windows. Apart from these deficiencies, however, the city seems to have been an imposing place with its solid-looking buildings, its many fine churches and its active commerce.

Our Queen City

Toronto's expansion during the fifty years has been equally, even if not more, phenomenal. When it is recalled that in 1867 Queen's Park, now in the heart of the city, was on its extreme northern edge, Trinity College was situated a mile beyond the western limits and that troops were able to go through extensive evolutions on a great common that lay between the city and Spadina Avenue, some faint conception of the physical growth of the place can be obtained. In population it has increased twelve-fold, or roughly from 40,000 to 480,000.

The cities in the east, Halifax and St. John, have probably exhibited fewer changes than their western sisters. Halifax, which has now about 50,000 inhabitants, had a population of 30,000 at the time of Confederation. St. John, which to-day contains approximately 54,000 people, was then a place of 35,000 inhabitants. In Halifax the lives of the citizens revolved around the garrison of British regulars which manned its forts and citadel. Some trading, it is true, went on with the West Indies. Fish was exported; sugar and other tropical products imported. But the military and naval interests of the place predominated and trade and commerce, while a necessary evil, were not allowed to thrust themselves too far into the foreground.

The commercial spirit was more in evidence in St. John, a city which then as now regarded its Nova Scotia contemporary with a feeling of suspicion and rivalry. St. John had been a notable shipbuilding centre for years and, not only was many a stout vessel built each year in its shipyards, but its merchants owned and outfitted numerous deep sea craft for service on the seven seas. The docks of St. John were a busy spot in those days, for ships and sailors were numerous and there was a constant coming and going of vessels from distant ports.

Industries Feature

If cities were small fifty years ago, so also were the industries that flourished in them. Industrially, there has been a remarkable change in Canada during the past half-century. When Confederation came into being the settled sections of the country were plentifully supplied with an immense number of small steel industries. Each town, each village, had its little group of manufacturing establishments which produced the essentials of life for the people of the immediate neighborhood. A flour and grist mill, a sawmill, a tannery, a carding and fulling mill, a carriage factory and not infrequently a brewery or distillery were the possession of practically every centre of population.

The census of 1861 showed that in Ontario alone there were in operation 501 flour and grist mills, 1,164 sawmills, 271 tanneries, 185 carriage factories, and 143 breweries and distilleries. In Ontario, Quebec, New Brunswick, Nova Scotia and Prince Edward Island combined, there were 8,503 industries, of which 1,785 were flour and grist mills, 4,240 sawmills, and 710 tanneries. By 1867 all these figures had probably been considerably increased.

Few of these primitive local industries have survived the evolution of the centralized factory system. Here and there through the country there may remain some pathetic examples of these once important institutions. But, generally speaking, the economies introduced in the operation of the large factories of to-day have made it quite impossible for the small industry to exist.

Lachine Canal an Industrial Factor

Even in the sixties there were evidences of the development of large-scale manufacturing. The building of the Lachine Canal seems to have produced a considerable industrial boom in Montreal. The canal furnished four million horsepower of hydraulic energy per annum, a huge figure for those days, and, as practically all manufacturing was done by waterpower, manufacturers naturally flocked to this new source of energy.

The extent and importance of the factories along the canal filled visitors with astonishment. There were huge iron works, employing no fewer than 120 men and producing 12 tons of nail plates per day! There was a wonderful new flour mill, which could grind 500 bbls. of flour in twenty-four hours. There was a sugar refinery with a capacity adequate to manufacture seven-eighths of the sugar consumed in Canada and there was a marine works, which could produce several ships for river and lake service each season.

One may smile at the expressions of amazement with which the citizens of 1867 regarded these examples of industrial enterprise, the size and output of which have long since been eclipsed by immensely larger establishments, but, after all, there were some industries in operation fifty years ago which would astonish even the wonder-sated folk of the twentieth century. The sawmills at Ottawa, for instance, were undoubtedly marvels. There were ten of them running night and day in an endeavor to keep pace with the efforts of the ten thousand lumbermen who were busy felling the forests along the river. One of these mills boasted eighty saws and the others were very little smaller. The ten mills together turned out 180,000,000 feet of lumber a year, while 16,000,000 cubic feet of square timber was rafted to Quebec each season for shipment across the Atlantic. In that golden age of the lumber trade, it took 800 ships, manned by 25,000 men, to carry the harvest of the Ottawa from Quebec to England.

Wood Shipbuilding

These were great and picturesque enterprises and so, too, was the wooden shipbuilding industry, which was in its heyday of prosperity when Confederation came into being. At Quebec and at many a harbor and port on the coasts of New Brunswick and Nova Scotia, fine, large wooden vessels were built and launched annually in considerable numbers. There were fifteen shipyards at Quebec alone, in which from 25 to 50 ships were turned out each year. Unfortunately, except for a forced revival of the industry at the present time, wooden shipbuilding is dead and thus an interesting chapter in Canadian industrial history is closed.

However, all industry in Canada in and about the year of Confederation was not so spectacular, though to the people of the time many of the developments seemed very wonderful. In Hamilton, for instance, where foundations for future industrial greatness were even then being laid, it was deemed a remarkable feat on the part of the local manufacturers to have installed $100,000 worth of new machinery in a single year. The production of locomotives at Kingston was considered a work little short of marvellous. The erection in Sherbrooke in 1866 of a woollen factory five stories high was heralded as a most important event, while Victor Cote's new tannery at St. Hyacinthe, which gave employment to 90 hands, was regarded as a mammoth plant.

But if industries were small and scattered, the products of industry were by no means inferior. At the great Paris Exhibition in 1867, the goods of Canadian manufacturers showed to advantage. Furniture made by Jacques and Hay in Toronto was declared to be superior to anything on display. The wall hangings of the Stauntons compared favorably with the product of the English makers. The Barbers, of Streetsville, showed cloths and woolens of most creditable quality. Implements from the Jones plant at Gananoque and the Whiting plant at Oshawa, were highly commended, as were also the cigars exhibited by Davis, of Montreal.

Transportation Developments

Industrially, Canada has traveled far since those far-away days. All the mar-

velous expansion which the introduction of electricity has facilitated has come since then. The mammoth textile works with their electric drives; the great steel plants; the huge paper mills; all these and many more have sprung into being since 1867, and in no respect has the progress of Canada been more marked than in this department of national life.

Hand in hand with the growth of industry has gone the extension of transportation facilities and rapid means of communication. In 1867 the railway systems of the country, since expanded into transcontinental proportions, were limited in scope. This was especially true of the Maritime Provinces, where the stage coach was still an established and very necessary institution when the Confederation era dawned Nova Scotia was served by two short lines of road, running from Halifax to Truro and from Halifax to Windsor respectively, a matter of some hundred miles of track in all. New Brunswick likewise had but two railways, one connecting St. John and Shediac and the other St. Andrew's and Woodstock. Prince Edward Island, which has now a system of 275 miles, was without any railway at all. In short, the three Maritime Provinces among them had only about 300 miles of road in operation, whereas today their mileage extends to 3,668 miles.

LOCK No. 1, NEW WELLAND CANAL.

THE DEEP CUT, A VIEW OF THE WELLAND CANAL IN THE EARLY DAYS.

The Upper Provinces were somewhat better served. The Grand Trunk, then the longest railway in the world under one management, ran from Portland, in Maine, to Sarnia, in Ontario, and from Riviere du Loup, on the Lower St. Lawrence, to Richmond, P.Q. Its most formidable rival was the Great Western, running from Niagara Falls through Hamilton, to Windsor, with a branch from Hamilton to Toronto. Northward stretched lines from Prescott and Brockville to Ottawa, from Port Hope to Beaverton, and from Toronto to Collingwood. All the rest of the network of roads now traversing both old and New Ontario were non-existent.

Railroad Through Traffic

The idea of through traffic was only just being evolved in 1867. The Great Western, then a wide-gauge road, as were most of the railways in Canada, had laid a third rail from Windsor to Niagara Falls and built a car ferry for service across the Detroit River, in order to secure a slice of the business between the newly developed settlements in the Middle West and the seaboard. The Northern Railway from Toronto to Collingwood was paying so much attention to the traffic it was receiving from the upper lakes and trans-shipping at Toronto for lower lake ports, that settlers along the line complained of the difficulty of getting their cordwood shipped to Toronto. In fact, the promoters of the Toronto & Nipissing and the Toronto, Grey & Bruce made it a point in soliciting financial aid from the municipalities that they would serve the settlers better in this regard that they were receiving.

Communication between the Maritime Provinces and the Upper Provinces in those days was usually by coasting vessel from Halifax or St. John to Portland and thence by Grand Trunk to Montreal. The extension of the Halifax-Truro road to Pictou, completed in the Confederation year, gave a new summer route up the St. Lawrence to Quebec, while one of the fruits of the new political arrangements between the provinces was the establishment of a line of steamers to run from Montreal and Quebec to Maritime Province ports. Otherwise it was possible to take a longer stage journey up the St. John valley from the railway terminus at Woodstock to Edmundston and across the height of land to Riviere du Loup, where the Grand Trunk terminated. This was the route by which the British regulars journeyed to Upper Canada at the time of the Fenian scare.

Victoria Tubular Bridge

The recent completion of the Victoria tubular bridge at Montreal was then filling the minds of visitors with awe and astonishment. It was hailed as one of the wonders of the world, a scientific achievement without a peer in the history of construction. Its three million cubic feet of masonary, its eight thousand tons of iron, its enormous length, its great cost, were dilated upon in unmeasured terms of admiration. For the times it was indeed a remarkable engineering feat, but since then many a far more wonderful undertaking has been completed in Canada, which illustrates still further how the country has progressed.

Canada's canal system had by 1867 reached considerable proportions and comparatively speaking, traffic by water was of more importance than that it is to-day. The lakes were covered with sailing craft, while steamboats were far more numerous than they are now. Of

course, all these vessels were so much smaller than the big freighters of the twentieth century that mere numbers were insignificant. At the same time they provided a most picturesque element in the picture of Canada in 1867. The passage of fifty schooners a day through the Welland Canal was by no means an unusual experience in the year of Confederation.

The canals were much smaller than they are to-day. Those on the St. Lawrence, by means of which ships passed up from Montreal to Lake Ontario, contained but nine feet of water, while the locks were limited to 200 feet in length. Notwithstanding this, records of vessels are not uncommon which had sailed down from the upper lakes and, passing through these canals, had later crossed the Atlantic.

Conditions of Travel

Traveling conditions in the year of Confederation were none too satisfactory. As compared with the luxury of the present day, a journey even for a short distance was an arduous and uncomfortable undertaking. In the Maritime Provinces, if a traveler preferred an overland journey instead of a trip by coasting vessel, he would have to put up with the inconvenience of a wearisome ride in a big, lumbering, springless stage over rough roads, his only solace the occasional pauses for rest and refreshment at old-fashioned change houses. In the Upper Provinces, he would have to contend with the wretched service of what were referred to at the time as the most poorly conducted railways in the world.

Two trains a day in each direction were sufficient to accommodate the traffic between the two largest Canadian cities. One made the journey by day, the other by night, and the run was scheduled for something like fourteen hours. The locomotives burned wood and there were frequent stops en route to re-load the tenders. Cars were small and light, the track poorly laid and the bumping and jolting terrific. One wretched tourist who endeavored to beguile the telium of the journey by a game of draughts found to his disgust that it was quite impossible to keep the men on the board.

Postal System

The postal system in Canada fifty years ago differed very little from the present system except that very much higher rates of postage had to be paid, and it took much longer for letters to reach their destination. The rate to points in Canada, that is, Ontario and Quebec, was five cents; to the United States, 10 cents, and to England, 12½ cents. A special weekly service to Halifax, via Portland, having been arranged, a business man in Toronto or Montreal could send a communication to Nova Scotion for the sum of 12½ cents. As for British Columbia, it cost 25 cents to forward a letter to the Pacific Coast.

Statistics for the year 1863 show that there were in the Upper Provinces, 1,974 post offices in that year and that the number of letters carried was 11,000,000. New Brunswick had 375 post offices, in which 833,625 letters were handled, and Nova Scotia 493 post offices, with 1,467,726 letters. The year's revenue for the three provinces was $853,778, and the expenditure, $896,303. As an indication of the extent to which the postal service has since expanded, it may be said that in 1915, the revenue for all Canada was over thirteen million dollars and the expenditure nearly sixteen millions.

Telephones

While the telephone was unknown in 1867, the telegraph and the Atlantic cable were both in existence, and so far as telegraphic communication was concerned, Canada was well served. Indeed, in Nova Scotia the boast was made that they had more lines of telegraph per inhabitant than in any other country in the world and, what is even better, lower rates. In Ontario and Quebec, the Montreal Telegraph Company, with over 3,000 miles of wire, controlled the situation, while in the Maritime Provinces the lines, about 2,000 miles in extent, were controlled by the American Telegraph Co. As there are to-day over 200,000 miles of wire in the telegraph systems of the country, it is obvious that here again there has been vast development.

The story of the telephone is all contained within the limits of the Confederation era. There were no telephones when Confederation was born. To-day there are between six and seven hundred thousand instruments in use, with over a million and a half miles of wire connecting them.

Electrical Street Railways

Electric street railways have been another modern development. In fact, in the year of Confederation, horse cars had only just come into use. Toronto's system had been opened in 1861. It consisted of six miles of track on Queen and Yonge streets, with eleven cars and 70 horses, a total investment of only $175,000. Montreal had also about six miles of track with similarly small equipment. Halifax was a third city with a system of horse cars at that time. The innovation was not welcomed. One critic complained that "the street railway is an institution for the benefit of those who ride, at the expense of those who drive, and is a flagrant violation of the rights of the majority. The horse railway is a permanent obstruction; it practically divides a wide street into two narrow ones and a narrow one into two lanes. It is questionable whether it will be found profitable in Canada."

In the light of this hostile attitude, it is interesting to note that the tiny systems in the three leading cities of 1867 have since developed into a vastly important series of electric lines, located in practically every city in Canada, operating upwards of 1,700 miles of track and carrying annually six hundred million passengers. The capital invested in them amounts to over $150,000,000.

Trade and Finance

Trade and finance have shown marvelous expansion in the fifty years of Confederation. When it is considered that in 1868 the country's total trade only amounted to a little over $131,000,000, of which $57,500,000 represented exports; that the export of manufactured products in that year scarcely amounted to $2,000,000 and agricultural products exported were under $13,000,000 in value, then the growth becomes all the more remarkable, for, in 1916, Canada's trade amounted to nearly a billion and a half dollars; her exports of manufactured products to $242,000,000, and her exports of agricultural products to $250,000,000. Her mineral exports in the same period jumped from $1,800,000 to nearly $67,000,000, and the products of her fisheries from $3,500,000 to over $22,000,000.

The development of trade has been graphically reflected in the expansion of the financial institutions of the country, notably the chartered banks and the insurance companies. There were as a matter of fact, more banks doing business in 1867 than there are to-day, but the banks of the Confederation year were very much smaller and, in several cases, they were in a notoriously shaky condition. In all, there were twenty-six of them in existence, with a paid-up capital among them of approximately thirty millions, or about a quarter of the paid-up capital of the twenty-one institutions now operating under Dominion charters. There were about 120 branches doing business, the large majority of which were located in the Upper Provinces.

Since 1867, sixteen of the twenty-six chartered banks on the list in that year have disappeared, either through failure or amalgamation, leaving but ten of their number to carry on the traditions of the pre-Confederation days. The survivors, in point of age, are the Bank of Montreal, Bank of Nova Scotia, Bank of British North America, Bank of Toronto, Molson's Bank, Bank Nationale, Merchants Bank, Banque Provinciale, Union Bank, and Canadian Bank of Commerce. Eleven new banks have been established, bringing the present total up to twenty-one.

To-day Canadian banks have over 3000 branches in Canada alone, not to mention agencies in the United States, the West Indies, and elsewhere. Their assets have grown since 1867 from seventy-five millions to well over two billions; their liabilities from forty millions to over eighteen hundred millions. They have deposits of over fifteen hundred millions as compared with twenty-five millions fifty years ago, and their circulation has expanded in the half-century from nine millions to over $132,000,000.

Insurance

Life insurance was the smallest of Canada's financial institutions in 1867. Only one Canadian company—the Canada Life, which had been organized in 1847—was operating, and the total insurance in force of all companies, including British and American, did not exceed $30,000,000. Progress in this one business alone has been little short of phenomenal. Company after company has been organized until to-day no fewer than twenty-six domestic companies are

reporting annually to the Dominion Department of Insurance, not to speak of fifteen British and sixteen American companies.

By the end of 1916, the insurance in force on the lives of Canadians amounted to nearly a billion and a half dollars, of which nine hundred millions was carried by our own Canadian institutions. The latter, whose assets in the year of Confederation were a mere bagatelle, now show accumulated wealth approximating three hundred million dollars; their annual income runs to over sixty million dollars; while they disbursed last year to policyholders or to their beneficiaries nearly twenty-five million dollars in cash.

The business of fire insurance has enjoyed a similar expansion. Our Canadian companies, then few in number and uninfluential, had at risk in 1867 about fifty million dollars, on which they were receiving premiums of somewhat less than half a million dollars and paying losses of from a quarter to half a million dollars a year. Last year, the domestic fire companies had $663,758,129 at risk, on which they were receiving premiums of nearly five million dollars, while they met losses during the year of over half that amount.

One might proceed and produce figures bewildering in their detail to demonstrate how far Canada has progressed in every department of business activity since 1867. The tremendous expansion of agriculture due to the opening up and settlement of the West; the development of mining, which is placing Canada in the forefront of the mineral-producing countries of the world; the growth of the fisheries; the extension of hydro-electric power in industry; these and a hundred other matters might easily be referred to as affording means of gauging the country's fifty years of progress. However, enough has been written to give a faint idea of the Canada of fifty years ago and with this in mind it is not difficult to picture mentally the extent of development.

CANADA'S COAL OUTPUT

THE Mines Branch of the Department of Mines, at Ottawa, has received from the principal coal mine operators returns of their production during the first three months of 1917, on the basis of which the following estimates have been made of total production during this period.

According to these estimates the total production of coal during the first quarter of 1917, was 3,590,991 short tons, comprising 1,233,934 tons in January; 1,143,956 tons in February, and 1,213,101 tons in March. Corresponding records for the year 1916 are not available for comparison.

The record would appear to show that the average rate of production in Nova Scotia and British Columbia was less than the average rate of production during 1916, but greater in the provinces of New Brunswick, Saskatchewan and Alberta.

The exports of coal during the three months' were 501,570 tons, as against exports of 737,744 tons during the corresponding period of 1916.

The imports of coal during the three months were 3,921,824 tons, as against imports of 4,002,892 tons during the corresponding period of 1916.

The production of oven coke during the first three months of 1917 was 308,690 tons—the imports during the same period being 207,139 tons, and the exports 5,606 tons.

Revised statistics for 1916, as compiled by the department, show that the total consumption of coal was 29,865,856 short tons, against 23,906,692 in 1915. Production in Canada was 14,483,395 tons, against 13,267,023 in 1915, and imports, 17,850,603 against 12,465,902. Production figures by provinces as given below show decreases in the East, but increases in the West:

Production by provinces:—

	1915 Short Tons	1916 Short Tons
Nova Scotia	7,463,370	6,912,140
New Brunswick ..	3,360,818	143,450
Saskatchewan ...	2,065,613	281,300
Alberta	240,107	4,559,054
Brit. Columbia ...	127,391	2,584,061
Yukon	9,724	3,300
Totals	13,267,023	14,483,395

PIPE COVERING

IT may be said that in most cases it pays to use the best commercial pipe covering obtainable, because where the material is paid for many times over during the first year by the saving effected by its use, the first cost loses much of its weight as a determining factor in the selection of type of covering to be used. In view of the results of thickness tests, it is a deplorable fact that few steam lines at the present time are provided with thick enough a covering for the greatest net saving. However, where fuel is cheap and the lines are in use only a small percentage of the time, the cheaper coverings have their advantages. Also, there are places, as on some heating systems, where the heat lost through the coverings is not wasted and the object of covering the pipes at all is to keep tunnels, etc., cool enough that men may work in them. Therefore, a careful study of conditions is necessary before a certain type of covering can be recommended for a given piece of work.

The durability of materials used for pipe coverings is a very important factor in determining the most economical covering for a given set of conditions. It has been pointed out that the proper basis for comparing costs is the cost per year and not the first cost of the material. This is true because the covering giving the greatest length of service for a given first cost and efficiency is obviously the one to select. In general, fibrous coverings are more durable than the molded forms; since the latter tend to revert to their original powdered state due to vibration and rough usage, while those made of fibrous material firmly felted together show no such tendency.

SUPPORTING HORIZONTAL RETURN TUBULAR BOILERS

THE method of supporting horizontal return tubular boilers is of more importance than is usually realized. Such boilers, no matter what their length or size, should be supported at no more than four points. If boilers are long it is common to support them at six points. In order to prevent the end supports from leaving their bearings, springs are often placed under the middle brackets, but this does not render the pressures on the supports equal and is only a makeshift. It is a principle in mechanics that if a body rests on three points, the pressures on these points can be determined and will not change even if the points change their positions or levels. A 3-legged stool adways rests properly on its legs, even when it rests on an irregular floor, but a stool with more than three legs never presses equally on each.

This shows that, in supporting a horizontal boiler, the three-point principle should be applied. To obtain this effect and yet have the boiler held up at four points, two points at one end are supported in the usual manner and the other two are connected by links to an equalizing lever working on a pin passing through overhead supporting beams. When a boiler is supported in this way, the stress in the plates due to the weight can be made proper, and will never change, no matter how much the brickwork may settle, but, if this system is not used, the stress at one point may be sufficiently great to be a serious matter.

BOILER RIVET HOLES AND RIVETING

RIVETING is now generally done by hydraulic machines, which have shown themselves superior to any other kind. In consequence of the slow movement of a hydraulic plunger, the rivets have time to enlarge and fill the holes; and from the solidity of action and steady holding power of the machine the plates are firmly pressed together, with the result that joints riveted by this type of machine are tighter than those made by any other.

It is a common practice to punch the holes of boilers ⅛ in. or ¼ in. small and then to drill them to size with all plates and covering strips in place. This is a great advance in practice over punching to size, but it is not satisfying to the imagination, and it may be one reason why plates exposed to the hottest gases crack between the rivets and their edges. Another reason for such cracking may be bulging caused by too much pressure by the riveting machine on the rivet. Sometimes such bulging is very apparent. A still further advance in practice is to punch one butt strap for each joint with small holes and use it as a template for drilling not only itself but the main plate and the other butt strap. Similarly, the holes in one plate of a circular seam may be punched small and used for a template for drilling the other holes. The best way, however, and the one which should be adopted everywhere, is to drill all holes from the solid.

Design and Constructional Features of Turbine Pumps *

By A. E. L. Chorlton

There are milestones in the history of the evolution of the centrifugal pump, yet the wide extent of its successful application in turbine form is due to the overcoming of practical difficulties, both mechanical and hydraulic. This work has only been accomplished after prolonged experience, and success has only been reached after tedious and careful study and improvement of small details. In what follows, there is described and traced the development of some of the methods of successfully overcoming the difficulties referred to, while attention is drawn to points in design which are the result of the author's experience, the latter extending back to the infancy of the Turbine Pump Principle in engineering achievement.

THE turbine has become so highly successful as a pumping engine for duties of all description, that no apology is needed for offering a few practical notes on the design and construction of its detailed parts. It will be convenient to consider the subject under the headings of the various component parts of a pump. These are:—

I.—The stator, which consists of (I a) the casing or housing, and (I. b) the guide vanes or appliance for converting velocity energy into pressure energy.

II.—The impeller (considered separately).

III.—The balancing appliance — hydraulic or mechanical.

IV.—The rotor, considered as a whole, and including the spindle with its projecting sleeves, impellers, and in most cases the balancing appliance.

V.—The bed, and other details, bearings, stuffing boxes.

Of these components III., IV., and V., broadly speaking, are the factors governing reliability and resistance to wear, and I. b, and II. are those determining the efficiency.

It is proposed to deal at greater length with III. and IV., for the reason that they have probably been less discussed than the others, also their practical importance is of the greatest moment, but the whole subject cannot be adequately treated within the confines of a paper written during the present time. The chief points only of items I., II. and V. will be briefly reviewed:—

I.—The Casing

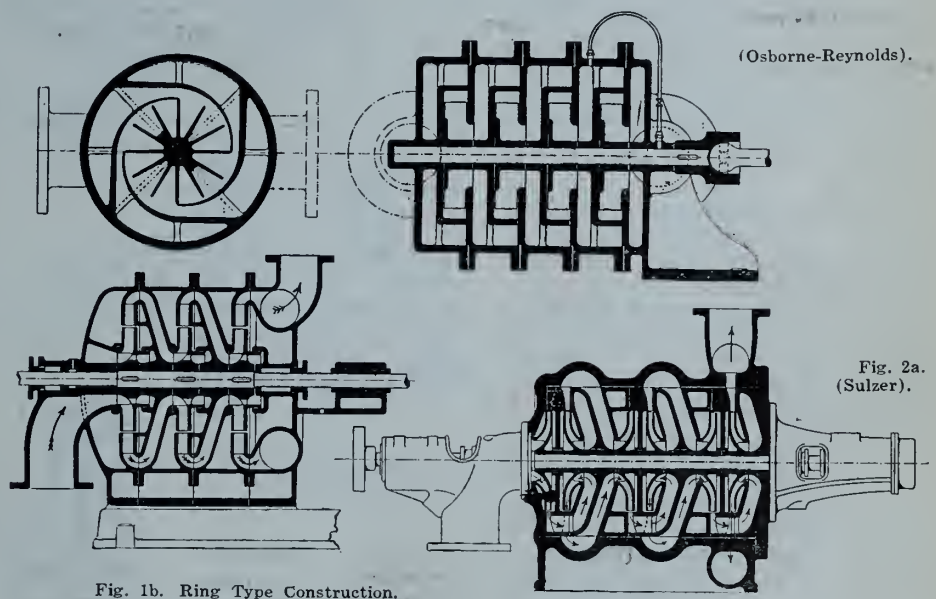
The individual impellers of a turbine-pump revolve in chambers or cells containing the outward flow guide-passages and the return conduits for the water; these chambers may be part of a whole in which the outer body is cast in one piece, or, an aggregation of a number of distinct cells without any outside envelope. There are, therefore, two main types:—

1—The Osborne-Reynolds or divided type, and sometimes called the "ring-type."

2—The Sulzer, integral or one-piece type, sometimes called the "cylindrical" type. Recent American practice provides a variation of this type with the housing in halves divided on the horizontal centre line.

The two main types are diagrammatically illustrated by Fig. 1 (a and b) and Fig. 2 (a and b), with variations in Figs. 3 and 4.

The Osborne-Reynolds pump and its evolution was dealt with by the author in collaboration with Dr. E. Hopkinson, in some detail in a paper read before the Institution of Mechanical Engineers in January, 1912. This type was followed at a later date by the integral one of Sulzer, which had, for a period, a considerable vogue. An examination of the present-day practice of various makers will prove, however, that the ring-type has ultimately proved the preferred one.



(Osborne-Reynolds).

Fig. 2a. (Sulzer).

Fig. 1b. Ring Type Construction.

SECTIONS SHOWING TYPES OF TURBINE PUMP CASINGS.

The Reynolds pump has always used a separate cell for each impeller, and it is therefore correct to say that the ring-type of pump owes its inception to Great Britain. The continental form of the series turbine-pump is due to Sulzer (first pump 1896); in this type a monoblock housing was used for all the chambers or cells, the guide-vanes being inserted from the end.

Before dealing with either type or variations arising out of them, it is advantageous to consider the essential functions of the chamber or housing of a turbine-pump. Primarily, each cell consists of (1) the outward flow guide-passages in which the kinetic energy of discharge from the turbine-impeller is converted into static head, and (2) the return water-passages back to the centre for conduction to the next impeller; a complete housing is a collection of such cells.

Obviously, in the design, commercial considerations must have a material guidance on theoretical claims. Against the requirements for best theoretical conversion of kinetic energy must be matched the allowable limits of dimensions conformable with commercial possibilities, and, in the interests of efficiency, special attention must be paid to the arrangement and dimensions of the divergent channels or guide-passages. As is well known, the form for guide-passages is represented diagrammatically by Fig. 5, and this passage must be disposed in some form to lie conveniently in the desired casing. The general character will be either a simple outward flow type in one plane, Fig. 6, or a mixed type outward and axial in two planes, see Fig. 7 (a and b) and Fig. 8.

The divergent angle of guide-vane, Fig. 5, for best efficiency was shown by Professor Gibson to be 10° to 11°. In many cases such a small divergent angle leads to a large overall diameter guide-vane in order to give a sufficiently reduced speed of water to permit reversing its radial direction, and the result is a very heavy casing in consequence. For this reason divergent angles of 15° are

*From a paper read before the Institution of Mechanical Engineers.

commonly found in practice. Evidently a more efficient pump will sometimes be heavier and more expensive than one less efficient, and commercial considerations must provide the final deciding factor between efficiency and weight. There is, of course, a school of design which believes in dealing with a proportion of the velocity conversion in the wheel itself, thus leaving less to be dealt with in the guide-passage; the extent, however, to which this method can be used for weight saving is very small, if any. The various assemblies of passages may clearly be grouped into:

A—Tangential and radial with return radial (see Fig. 6 and Fig. 1, b).

B—Tangential and spiral (see Fig. 7 (a and b) and Fig. 8).

C—Combinations (see Figs. 9, 10 and 11).

The Osborne-Reynolds pump (1887 and 1875 type) employed an early form of the B assembly, and has adhered to this type up to the present day, various improvements being embodied from time to time, in some of which the author was concerned. On the Continent of Europe, Messrs. Sulzer introduced in 1896 design A, and the author believes they have made little departure from the type beyond a considerable simplification of their early arrangement of passages. Fig. 2 a Speaking generally, combination designs C are not so efficient as the simpler types A and B, owing probably to the hydraulic loss through changing the radial direction of the water at high speed.

From a works construction point of view, "ring casings," Fig. 1 (a and b), are the most economical, and in practice give high efficiency. In the form similar to that shown in Fig. 12, the author some years ago was able to mould and cast ring-casings without cores, machine moulding being adopted, and the cost per chamber coming out at a very low rate.

For "cylindrical" casings, Fig 2 (a and b), a complete pattern is required for each size and variation in number of chambers. Its accessibility, however, and ease of dismantling is sometimes considered to be greater than with the "ring" type, though this is, to a certain extent, a matter of opinion. A great drawback to casings containing separate cells is that, on account of the sliding fit between the intermediate pieces and casing, an unknown amount of leakage constantly takes place between the cells. With a "ring" type of pump, leakage is instantly detected and can be remedied. As a commercial proposition the author unhesitatingly favors the divided or "ring" type of casing, and when properly carried out, has met no difficulty with it in practice.

Fig. 2b. Continental pump—cylindrical casing construction.

Fig. 4. Combination of cylindrical and ring features.

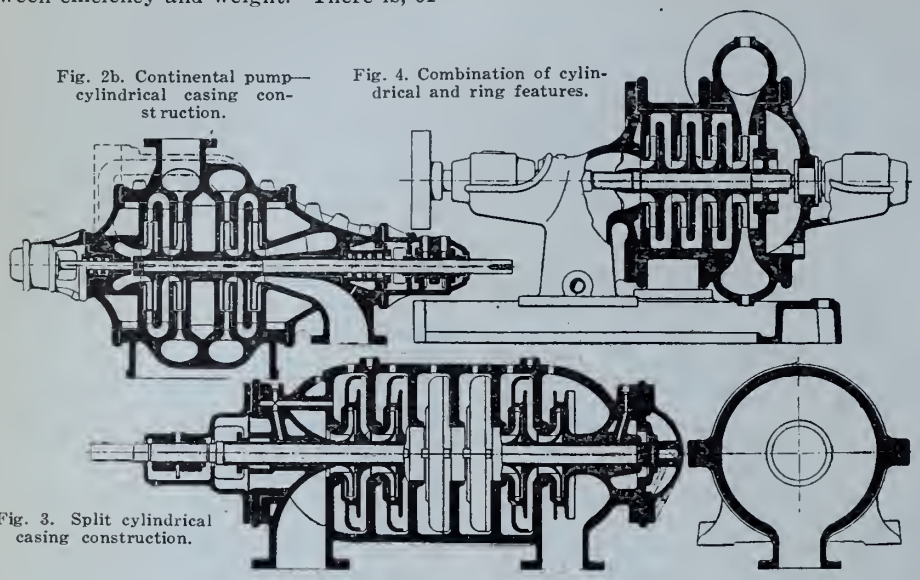


Fig. 3. Split cylindrical casing construction.

SECTIONS SHOWING TYPES OF TURBINE PUMP CASINGS.

Finish of Guide Passage Surfaces

Before leaving this part of the subject, a word about the finish of guide-passage surfaces is necessary. For best efficiency the throat of the passage at least, if not the entire passage, should be gun-metal or bronze, as iron does not preserve a sufficiently good surface for high velocity conditions. Common practice is to provide only three sides of the guide passage in bronze, Fig. 13, but this can only be defended on grounds of cheaper first cost. For best results a bronze-plate should be provided to box-in the passage, the plate being attached to the guide-vane casting or dowelled to the casing. Guide-vanes are sometimes cast completely boxed in, and this method necessitates hand finishing of the passage by file and scraper; open vanes, however, lend themselves better to cleaning out and accurately finishing either by hand or by machining. A good smooth surface is essential for the best results and will always justify the increased cost. The method adopted of securing guide-vanes from rotation and vibration must be a thoroughly sound one or trouble will result.

II.—Impellers

Impellers are either single entrant, or double entrant. The first is almost universally in use for multicellular pumps, and the second almost exclusively for single-chamber pumps; it is only proposed to deal with the single entrant form. Multicellular pumps use the single-eye wheel in three forms:—

(a)—Unbalanced, unequal side area, one rubbing shoulder, Fig. 14.

(b)—Unbalanced, equal side areas, two rubbing shoulders, Fig. 15.

(c)—Balanced—on paper, Figs. 16 and 17.

There are other types, mixed flow, radial and axial, etc., but these are not used to a sufficient extent to be worth including in this paper.

Type (a) may be said to be the one now generally used, that is, the preferable design.

Type (b) has certain advantages for machining, etc., but probably requires a stiffer shaft. Also, having no central sup-

ports, it tends to rotate the suction water of the next impeller and may be attended by greater stage leakage due to the increased annular running clearance.

Type (c) has the paper advantage of being in balance; actually it is a poor approximation to a balance. Disturbing factors are set up by: differences in side pressure on the impeller due to differences in volume and surface-form of the water contained on the two sides of the impeller, Fig. 18; difference of quantitative leakage through the two shoulders; and high-pressure leakage into one side of the impeller from the stage above, and leakage from the other side of the impeller to next low pressure stage below. Therefore, in practice, it is necessary to provide an additional end balancing device of the hydraulic type, or a mechanically positioning fitting such as a thrust-collar or ball-bearing; a method, especially for mine usage, not to be recommended.

The internal design of all impellers is governed by the same controlling features:—

power and size of motor, the combination will generally come out cheaper.

The maker who elects to change his impellers and diffusers to suit the demands of the inquiries as they come in, will obtain a higher percentage of orders than one who has standardized his, even though the latter may have reduced costs by making in large quantity. In considering if in any way it is possible to meet the designer's requirements without losing all the advantages of repetition manufacture, we may first take the in-

SECTIONS OF TURBINE PUMPS SHOWING COMBINATION PASSAGE ASSEMBLIES.

1.—The entrance or inlet angle of vane.

2.—The delivery or exit angle of vane.

The entire design must, while based on these considerations, consult the convenience of the workshop to the utmost degree possible without departing from required dimensional accuracy. The standing difficulty with turbine-pumps, from the manufacturing point of view, is their constant variation to meet the infinite number of conditions of varying head, speed, and quantity encountered in practice. Whatever efforts are made, it seems impossible to keep to a small number of standard impellers if the highest efficiency is to be reasonably well reached each time. Efficiency, it should be noted, is really the prime factor in design and not apparent first cost, for the pump is very often driven by an electric motor of greater value. If, therefore, by the use of a pump of higher efficiency, a reduction is effected in the necessary let angle. This depends on the resultant of the (supposed) radial flow of the entering water and the peripheral speed of the inlet tip itself, and it usually varies between 15 degs. and 30 degs. If we select to use always 15 degs. we might suffer in some cases to the extent of 3 per cent. or 4 per cent. If we take two sizes, 15 degs. and 25 degs., and make a liberal provision of inlet width, or, as some designers phrase it, make an adequate allowance for "weir coefficient" at entrance, we shall only drop perhaps 1 per cent. in exceptional cases; so it seems possible to do something in the way of standardizing the inlet angle.

Current Ideas Concerning Inlet Angle

One might refer, in passing, to some of the current ideas concerning the inlet angle and the condition of the water at entry to the impeller. Some designers have maintained that very great accuracy of the inlet angle is vital to high efficiency, in spite of the fact that in the ordinary unobstructed eye it is impossible to say what the absolute velocity and direction of the incoming water is, and therefore, to estimate precisely what the correct inlet angle should be is impossible. Further, the behaviour of the incoming water varies with every rate of flow, and the only way to foretell its condition would be to insert inlet guide-vanes; this, however, in such experiments as the author is aware of, has proved an objectionable practice and only introduces further losses in the pump. Another school holds that it is an advantage purposely to introduce a forward whirl in the water at the eye with the object of helping the water into the impeller. If such an initial whirl is used, the work necessary to create it is necessarily done by the pump itself, and it is, therefore, questionable if this does not entirely overweigh any possible gain.

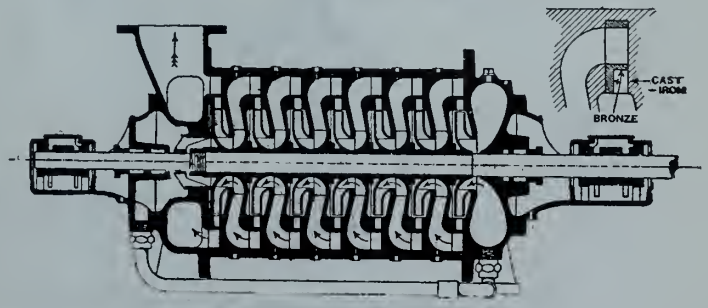

FIG. 13. (FARCOT).

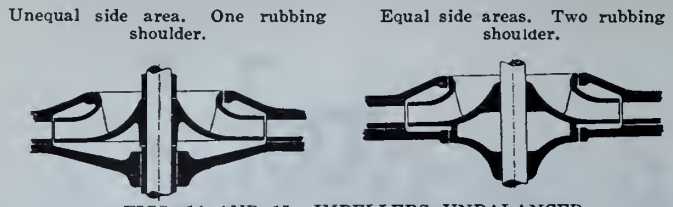
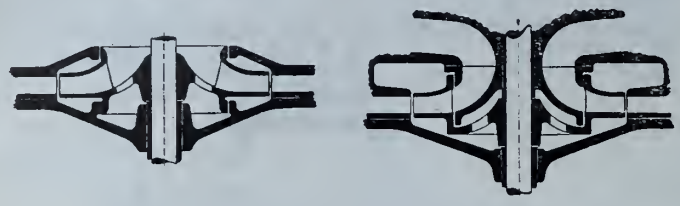
The discharge angle depends on the resultant of the peripheral speed of the wheel and the radial out-flow, the variation of which is so great it seems impossible to devise any standardization. To meet quantity variation two widths of impeller may be used, and to meet required speeds of revolution it is usual to allow a small percentage variation in the impeller diameter to suit special demands; this latter, however, is conveniently done without pattern or casting alterations.



FIGS. 14 AND 15. IMPELLERS UNBALANCED.



FIGS. 16 AND 17. IMPELLERS BALANCED.

The foregoing considerations lead to the conclusion that nothing less than a special core-box will be required for each case, and it is quite usual to meet the difficulty in this way. Evidently, however, a most valuable appliance would be a special form of core-box, which in itself was more of a standard and could be adopted for manufacture in quantity; this result might be effected by fitting in vanes of a flexible nature, so that the necessary alteration and adjustment would not be great, and the whole outfit would come out cheaper than if a pattern-maker had to build a fresh box and fittings for each new demand. As the accuracy and smoothness of the impeller is of great importance, the author has always looked to machine moulding, and to a special machine like a wheel-moulding machine, for the purpose; he has not, however, as yet, arrived at the final design for such.

Impeller Surfaces

The surfaces of the impeller, both inside and out, play an important part in the efficiency of a turbine-pump. The smoother the outside surface the less the power lost in disk friction, and the less the power wasted in revolving idle "dead-water." An interesting point to note is that the greater the speed of revolution of the "dead-water" (that is, the greater the power absorbed in this way), the less the leakage from the periphery of the impeller; but a little consideration will show that greater overall economy is gained by reducing the wasted power in idle revolution to a minimum. As regards the internal smoothness of the passages of the impeller, it is usual practice to clean up the surfaces as well as possible with file and scraper. Impellers have been built up with one loose side so as to permit of machining or more effectively cleaning the interior; and it is evident that with individual impellers producing high heads the results would well repay the extra cost. Objections to this practice are the difficulty of making attachment of the two parts and the extra weight necessary to provide attachments.

FIG. 18. EFFECTS OF GYRATORY PRESSURE ON END THRUST.

III.—Balancing Appliance

The experienced designer knows, from practical knowledge, that even if a group of impellers, or even a single impeller, is theoretically balanced by equivalent areas subject to pressure, it will not in actual practice be free from all end thrust. Apart from variable leakage at the two sides of an impeller, which, by the way, is the principal cause of end thrust, we often have variable side surface both of the impeller and the cell chamber. If the conditions of capacity or surface of the two clearance-chambers vary, the resulting pressures will vary and an axial thrust is set up. Professor Gibson has investigated the effects on efficiency (power lost) due to varying the side clearance of the impeller, and he took readings of circumferential pressures set up by revolving disks, but he apparently did not plot out the resultant effect in end-pressure. This interesting problem is discussed in a paper by F. Zur Nedden, where use is made of the results from both Professor Gibson's and Professor Unwin's revolving disk experiments. The general effect of the gyratory pressures set up is indicated in Fig. 18. It is seen that the speed of the revolving "dead" water at the two impeller sides sets up pressure in opposition to the leakage pressure from the impeller-tip, as already pointed out; the faster the water revolves the greater the resistance to leakage, and the less the resultant pressure due to that leakage. It can readily be seen, therefore, that the effect of the chamber at one side of a wheel having greater capacity than the other, or having more obstructions in the way of ribs, pockets, or exceptional roughness, etc., plays some part in the determination of end-thrust.

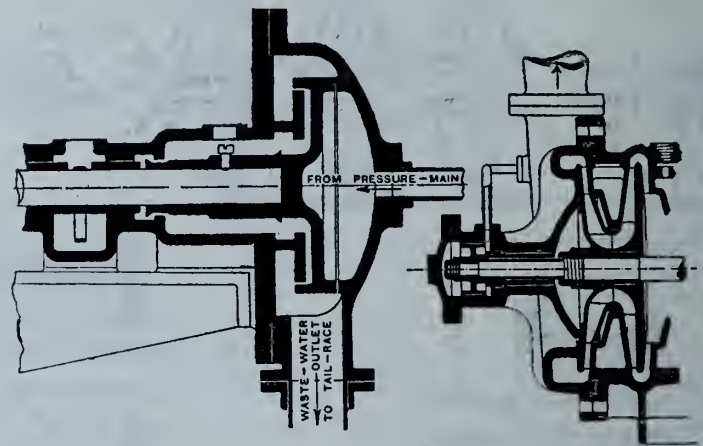

FIG. 19. HYDRAULIC AXIAL BALANCING DEVICE (FRANCIS).

FIG. 20. PUMP (RATEAU) SHOWING HYDRAULIC COMPENSATOR.

All the earlier turbine-pumps employed some form of thrust bearing, either of the collar or the ball type, to keep the impellers in correct alignment with the guide passages, and it was not until much trouble had been experienced with these that hydraulic control was ultimately adopted. Experience showed that much higher end pressures were set up than were ever anticipated, but for a period

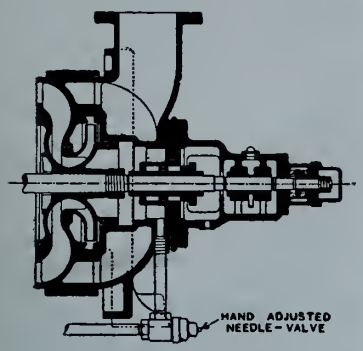

FIG. 21. HAND ADJUSTED BALANCER.

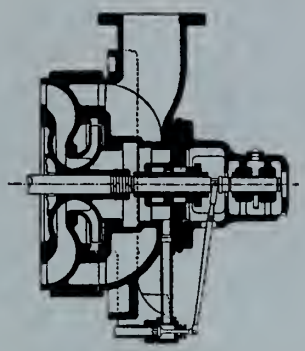

FIG. 22. MECHANICALLY ADJUSTED BALANCER.

mechanical devices were persisted in, improvements being made attempting to withstand the excessive loads, and scant notice, it would appear, being taken of water-turbine practice where for many years it had been the custom to relieve axial thrust hydraulically. Fig. 19 illustrates an hydraulic balancing device in use on Francis turbines, and which, if properly proportioned, is automatic, and thus embodies all the essential points of many present turbine-pump balancers. One should bear in mind that the relation between the calculable axial thrust and the thrust realized in a water-turbine is much closer than in a centrifugal pump of the multi-stage type, the reason of this being that the disturbing factor in a high-lift pump is the leakage from stage to stage.

The well-known application of turbine-pumps to high lifts by Messrs. Sulzer at Horcajo Mines in 1898, was carried out with back-to-back impellers, and a ball thrust-bearing was provided to take the end-thrust (in one direction only), which is inseparable from this arrangement of impellers. In 1901, Professor Rateau was manufacturing pumps with end-thrust approximately eliminated hydraulically by his well known method of shroud reduction, and provided with a balancing piston, Fig. 20. This method was not automatic, and the pressure on the piston could only be adjusted by means of a hand-operated throttle-valve. However, this was the first step, and the automatic control of the necessary pressure on the balancing device and determined by the end movement of the spindle followed as a matter of course. The development of the differential type of balancer carried out under the author's direction in 1913, extended over several years, progressing step by step from a hand-adjusted needle-valve, Fig. 21, regulated to produce the required balancing pressure, to a mechanically-operated needle-valve, Fig. 22, actuated by the axial movement of the spindle, and then through several forms of rotating throttle-valve disposed on the spindle itself and actuated by the same means. Further reference to the final balancing appliance (diagrammatically shown in Fig. 23) will be made shortly.

In 1906, Messrs. Sulzer brought out their device for relieving thrust shown in Fig. 24, and the principle used has been followed by many other makers and introduced with many variations. The action of the Sulzer device is simple; it comprises a single plate with a throttling device, through which the pressure water has access to the plate. The area of the plate is sufficient when acted on by a somewhat throttled delivery-pressure to overcome the tendency of the rotor to travel in the opposite direction. As the pressure gradually rises before the plate, its increased power carries the rotor to the right until further motion is arrested by the escape of the increased pressure through a widening annular space between the plate and its facing seat. An ultimate running position is reached when the leakage through the clearance between valve and seat is sufficient to maintain a pressure at the back of the plate, equal to the set of the rotor in the opposite direction. It will be seen that the balance is quite automatic in its control, end-movement in either direction taking place until stability is reached.

Without going further into the detailed evolution of automatic control of the hydraulic end-balance of the turbine, it is sufficient to say that the devices adopted resolve themselves into two basic forms:—

(a) Single acting (simple), of which the Sulzer, Fig. 24, is the general type.

(b) Double acting (differential), of which Fig. 23 is the type, and Fig. 13 a modification.

Other single-plate forms are shown in Figs. 25 and 26. In the first of these the throttling agent, a small nipple, is removed to the discharge side of the plate, thus giving, in a measure, a double action to the plate; the quick action and limited travel due to the second face of the differential type is not obtained, however, and there is a possible disadvantage in the small aperture when dealing with impure water. The second example combines some of the points of both forms of balancer, but as the pressure in the spent-water chamber is always augmented by high-pressure leakage into the low-pressure side of the plate, the device is, obviously, relatively extravagant in leakage water, and must therefore be considered inefficient.

The general effect of wear on single-plate balancers is increased leakage, the outcome of which is further end-movement in one direction until finally the impeller discharges do not match their guide-vane entrances, but become off-set. This tendency in hydraulic balancers led the author to devise form "b," or the double-action control with which such difficulties are overcome.

Fig. 23 (also in Fig. 12), finally shows the present standard double-plate or compound differential balance arrangement. The balance-piston and regulating valve are combined, and form a balance-disk with two active throttling surfaces floating between two fixed seatings with a minimum clearance. All the working faces are arranged vertically so as to be independent of possible vibrations of the rotary system. The pressure-water, escaping from the rim of the last impeller, passes through the holes h, into the pressure chamber m, from which it escapes along the throttling surface of the balance-valve into the regulating pressure-chamber k, and from there, past the

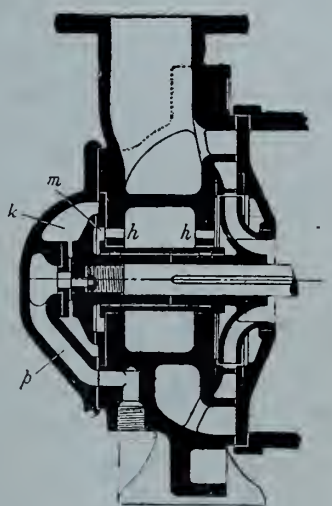

FIG. 23. DIFFERENTIAL HYDRAULIC BALANCER.

FIG. 24. SINGLE PLATE BALANCER (SULZER).

small throttling surface into the escape-pipe p, leading preferably to an open drain, or, back into the suction-chamber of the pump. The double-plate balance appears to be the most sensitive automatic balancing device in practical use, for by it, closing up of the plate on the

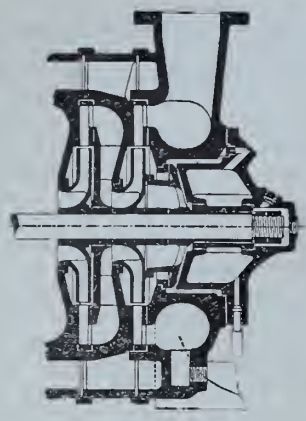

FIG. 25. (MILLINGTON.

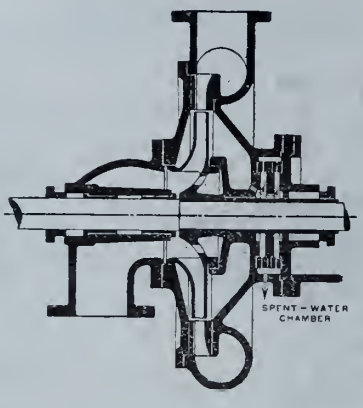

FIG. 26. (SCHEURMANN).

SINGLE PLATE BALANCERS.

large throttling face causes an opening out on the small one, thus multiplying the balancing effect; a movement of a thousandth part, or so, of an inch being all that is required to counterbalance the most extreme and sudden changes of the hydraulic equilibrium of the pump. The other and most important feature of this auto-plate balance is that it always maintains the central position of the impellers, even if the throttling surfaces become worn, as is invariably the case when pumps are working on gritty water.

A continental form arising out of this type is shown in Fig. 27, and it is obvious that the same remarks concerning extravagance in leakage water apply to this example as to Fig. 26. The arrangement of the balancer at the end of the spindle outside the external bearings is not a good one, for the reason that a high-pressure gland at the delivery end of the pump is still required, and an additional gland also for the balancer-housing. A single-plate balance made by the same firm as the above is shown in Fig.

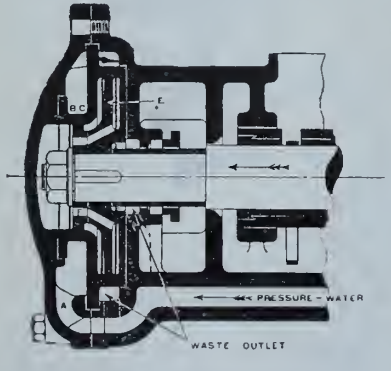

FIG. 27. DIFFERENTIAL.

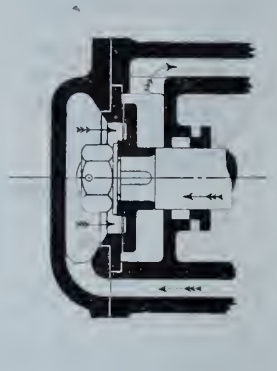

FIG. 28. SINGLE PLATE.

CONTINENTAL HYDRAULIC BALANCERS.

28, and this, too, is open to the same objection as regards disposition on the spindle.

It is usual to make hydraulic balancers with renewable faces at the points of close-running, so that the appliance can be readily repaired after wear has taken place. As regards the best material to be used for the renewable part, some considerable experience is needed before a decision can be made. Gun-metal was probably the first material to be used, but cast-iron, cast-steel, and hard bronze have all been tried, the present practice usually being to fit hard bronze. The ideal material is one which is hard and "short," and has a very low coefficient of friction when working in water; a material which "drags" is quite unsuitable, and apparently an incorrodible iron, one containing a high percentage of silicon or a nickel steel, seems to best fit the requirements. Non-metallic substances, such as red-fibre, woodite or dexine, have been considered, but any material which becomes slightly absorbent after long immersion is useless.

Sometimes difficulty is experienced in starting up large turbine pumps on account of the large diameter balance-rings being held together in metallic contact instead of being apart in their usual running position; the result is an abnormally high starting torque for the motor and probable damage to the faces of the balancing device. When a turbine-pump with differential balancer is "stopped," the rotor will always take up a position with the balancing faces apart if the waste-water outlet (Fig. 29), is taken to an open drain; however, if the spent water is led back to the suction pipe of the pump and a foot-valve is provided at the end of the suction-pipe, the whole rotor is forced towards the suction-end of the pump as soon as the foot-valve closes and the head pressure comes on. The reason for this is that the area of the balances on the outlet side is greater than on the inlet side by an amount equal to the diameter of the spindle. For this reason, the waste water from a balancer should not be connected to the suction-pipe of a pump, or means should be taken in the pump to equalize the areas subject to the static hydraulic pressure (Fig. 12).

IV.—The Rotor

As is well known, the internal design of a multi-stage turbine-pump involves a rotor comprising a number of impellers keyed on to a shaft, the shoulders or bosses of which abut on each other and are secured and maintained together by double nuts or the like at, or near, the ends of the shaft. Such portions of the shaft as are not covered by the impellers, but are subject to the action of the pumped liquid, are protected by sleeves which fit up to the impeller bosses and thus make a complete sheath outside the shaft itself, Fig. 1 (b), and Fig. 2 (a and b), etc.

This rotor revolves within the guide-chamber and housing, each impeller running at some points in the closest proximity to the partitions dividing the pressure-stages and return-guides.

These so-called running joints or neck-rings must be so maintained by design and construction as to secure in continued service the smallest possible hydraulic leakage-back from stage to stage, or mechanical loss by rubbing friction, both of which effect the efficiency and wear and tear of the pump. As a question of practical importance, the design of this combination probably follows next to that of the successful automatic hydraulic balancing of the axial end-thrust. We have in it the question of the deflection of the pump-shaft; the reinforcing effect of the surrounding impellers; the support afforded by the bushes, if any, between each stage, and the loss by bush friction (wear); the form of neck ring to reduce leakage; and the effect of keyways and keys, etc., all independent of each other and affecting the whole.

The ideal condition is that of a rotor supported in lubricated bearings with a shaft of such sufficient stiffness between supports that the deflection, under all possible running conditions, is less than the clearance allowed at the neck rings and intermediate bushes, so that no contact takes place between the rotating and the fixed members, this clearance at the neck-rings and intermediate bushes being kept down to the smallest possible limit. It will be seen that it is impossible to present mathematically, the exact conditions with such a number of incalculable factors to take into account.

For instance, it may be thought that a not inconsiderable reinforcing effect is obtained by the combination of the impellers outside the shaft as a whole. In practice, however, it is not advisable to lock up the impellers together shoulder to shoulder against each other by the

end-nuts in order to get the advantage of the reinforcing effect; because, due to, amongst other things, the slight inaccuracies of manufacture in squaring the shoulders of the impellers, sleeves, etc., the result would be to throw the combination out of truth, that is, to distort the shaft.

It might be contended that this need not be so, but even then provision must be made for dismantling in a mine or similar place, with its obvious attendant disadvantages, and the possibility of rough treatment taking place; furthermore, as a safeguard against heating up and consequent expansion of the outside combination (bronze) against the internal (steel) shaft due to accidental contact with the intermediate bushes, running, perhaps, when the pump is empty, suitable expansion should be allowed for, and the impellers, to ensure this, must not be locked tight against each other.

The supporting effect of the bushes on the shaft, in passing through the diaphragm intermediate between the impellers, is very difficult to exactly allow for; it may be that the bushes will decrease the deflection of the shaft by a material amount, but it must not be assumed for one moment that they are bearings of such a nature as lubricated bearings. Intermediate bushes can only, in some cases, be considered as water-lubricated supports which will act as such so long as a certain low surface pressure on them is not exceeded; if too great pressure comes on, heating takes place on account of the high speed of rotation. The effect of wear has also to be taken into account for the hydraulic pressures at the two ends of these bushes are different and there is, therefore, always a flow taking place through them, carrying with it any sedimentary or foreign cutting matter which may be in the water. This state of things causes the supports to wear more or less rapidly so as to become almost useless, the pump eventually arriving at a condition worse than if a suitable clearance had been allowed at the first.

The author believes that too much use is made of these intermediate supports in turbine-pump design. It is found in practice that an internal bearing to be successful must have the same water pressure at both ends, and must be properly lubricated with good grease, it then gives excellent results. We are thus left with the fact that we are practically dependent on the shaft itself for the necessary strength and stiffness to allow of fine internal clearance, and the importance of a good design which will economically give the minimum deflection of spindle at once becomes apparent. The factors affecting the deflection of a turbine-pump spindle are:—

Static

(a)—The weight of spindle and distribution of diameter change;

(b)—The weight and distribution of impellers, balancer, and parts;

(c)—The number and span of supporting bearings; and

Dynamic

(d)—In the dynamic condition, other incalculable forces entering into the account, such as, centrifugal forces due to the out-of-balance masses, and finally certain hydraulic disturbances.

(a)—Should be as light as possible consistent with the necessary stiffness; in common practice spindles are practically parallel the whole length.

(b)—Impellers and balancer should be grouped together as closely as possible, only allowing sufficient space for the water passages between the stages; also, the entire weight should be brought as close to the supporting bearings as possible.

(c)—The span of supporting bearings plays such an extremely important part in the durability of the pump; in the possibility and preservation of fine clearances; in the whirling of the shaft, and in the determination of the most economical size of spindle, that special notice will be taken of it.

(d)—A loaded shaft supported horizontally between two bearings will "sag," and when rotated must suffer bending at every revolution. Also, there are bound to be certain out-of-balance masses in the rotor due to keys, heterogeneous composition of material, and the unavoidable variation in thickness of castings, etc. In addition, a shaft has vibrational periods due to its length and diameter, the whole question of vibration being intensely complicated by the loading and supports.

In addition to the disturbing factors mentioned above, vibrations are set up from the reaction of the impeller vane passing the guide vane. It is usual to reduce the intensity of this disturbance by arranging an odd number of vanes in the impeller relative to the guide vane, and by setting successive impellers on the shaft in such a way that the point of passing-vanes is progressive throughout the series, i.e., a "lead" is given. The resultant of these arrangements is to produce a vibrating influence, which may be torsional or combined torsional and transverse, of very high frequency and enfeebled intensity and which, when properly carried out, is free from practical disadvantage. The damping effect of the water film in neck bushes is appreciable in overcoming slight vibrations, as is conclusively shown by the different behaviour of a spindle when running a pump dry and when running it filled with water. In order for a shaft to oscillate, it must force liquid out of one side of a neck-ring, and the retardation offered by this action has a noticeable effect. For this reason, quite apart from the lubricating effect gained, it is always a wise precaution to fill a pump with water before running it, otherwise if the shaft is not a stiff one seizing-up will probably occur. The remedy for spindle vibration due to any cause whatever is always a stiff shaft.

The whole matter of whirling shafts has been examined by several investigators, prominent among whom is Professor Dunkerley, but it is not proposed to discuss the matter further than to refer to the general proportions affecting the critical speeding of whirling. We find that the length (l) of span of bearings, and the diameter (d) of the spindle have an effect varying as:—

$$\frac{d^4}{l^3}$$

Turbine-pumps do not usually run at speeds approaching the critical speed, but the maximum safe speed for any rotor will bear a direct relation to the critical speed, in the sense that it will be an equal factor for equal safety. The above relation shows then, that for a fixed critical speed a reduction in the span of the bearings results in a material reduction in the necessary shaft diameter. The effect of axial thrust—always present in a turbine-pump—in lowering the critical speed of a spindle should always be borne in mind. With a view to consider-

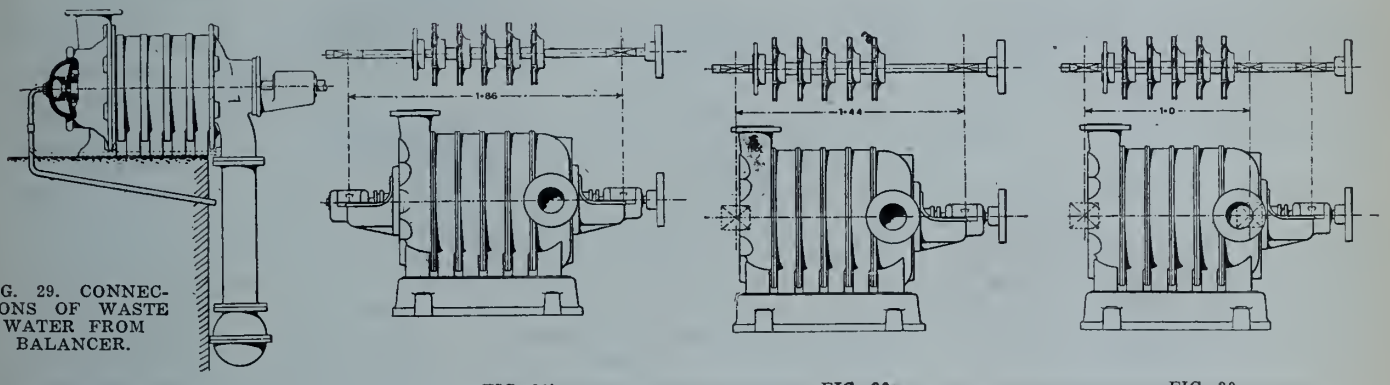

FIG. 29. CONNECTIONS OF WASTE WATER FROM BALANCER.

FIG. 30b. FIG. 30a. FIG. 30c.
SPAN OF BEARINGS—THREE ARRANGEMENTS.

ing the effect of the spindle diameter and span of bearings on the degree of fineness of the running clearances, we will examine the extent of the deflections. The following arrangements of bearings are possible and are illustrated in Fig. 30:—

1.—Two outside bearings.
2.—One outside and one inside bearing.
3.—One outside and two inside bearings.

A typical example was taken, and it was found, after drawing out the different arrangements, that the ratios of the spans of the bearings supporting the loaded shaft were, for the three cases, 1.86, 1.44, and 1 respectively, calling the shortest span unity.

As the deflection of a circular spindle is proportional to $\frac{l^3}{d^4}$, the deflections themselves for the above spans are proportional to 6.5, 3, and 1 respectively, or, the necessary sizes of spindles to maintain the same deflections are proportional to 1.6, 1.3, and 1. These results are conveniently tabulated:—

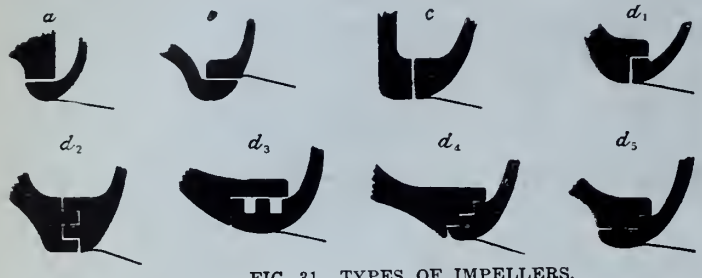

FIG. 31. TYPES OF IMPELLERS.

Case.	Ratio of span.	Ratio of deflections.	Ratio of spindle diameter to preserve constant deflection.
1. Two outside bearings. Fig. 30a	1.86	6.5	1.6
2. One outside and one inside bearing. Fig. 30b.	1.44	3	1.3
3. Two inside bearings. Fig. 30 c.	1	1	1

It will be noted that no allowance has been made for the buoyancy of the medium (water) in which the rotor revolves. The great importance of keeping the distance between bearings in a multi-stage turbine-pump as short as possible is aboundantly clear from the foregoing, for, with the more or less customary type, Case 1, Fig. 30a, with outside bearings at each end, it is seen we have a deflection of six and a half time that of a pump with two internal bearings. The direct result of this extra deflection is that the clearances between the outside of the eye of the impellers and the neck-ring must be increased to allow of the impellers revolving without touching, and this increased clearance necessarily means a correspondingly increased leakage and loss of efficiency.

Further, as has been shown, the passage of a large volume of water through the running clearance means increased wear and a tendency to push the walls apart, and therefore force the impeller and shaft still farther out of the straight with consequent friction against the adjacent neck-ring surface. Dynamic out-of-balance may, and, very probably, will exist, even though considerable care has been taken in the workshop to overcome it; this factor is a very important consideration, and calls for a very stiff shaft to resist its possible occurrence, because, if the shaft and impellers are thrown out due to this, then further clearance at the neck-rings is necessary or abrasion will result. The question of the reactive effect of an impeller discharging unequally round its circumference is capable of so many variations that the only practical way to overcome this also, is a mechanical construction that will resist deflection, that is, a stiff shaft.

There is a further disturbing influence which is more active in smaller pumps, namely, the effect of the hand-packed and often ill-adjusted stuffing-box and gland; this detail is always standard for one end of the pump, and sometimes found at both suction and delivery ends. Apart from the cutting effect of such a packing on the shaft or its sleeve, it also, by reason of its compression in screwing up, tends to set the shaft out of the true centre, and so may intensify many other similar influences. The risk of outside bearings, separate or overhung, being slightly out of centre, must also not be forgotten. For very many reasons, therefore, it is extremely important that the distance between bearings be kept as short as possible, and to do this successfully, internal, specially designed, large diameter, grease-lubricated bearings are essential. Summarizing the effect of a long distance between bearings, we have:—

(a)—Increased deflection of rotor.
(b)—Increased neck-ring clearance.
(c)—Increased leakage from delivery to suction.
(d)—Increased wear thereby, and
(e)—Decreased efficiency.

Turning now to the dimensions of the rotor, the table shows the diameter of the shaft does not increase as fast as the length of span increases. However, a very serious increase in size (1.6 times) is entailed by the increase in span consequent upon changing from two internal bearings to two external bearings. Obviously increasing the diameter of the shaft will give the decreased deflection desired, but then it introduces a larger diameter of impeller boss and entrance eye, thus bringing about a corresponding drop in efficiency as well as more leakage owing to the larger leakage area

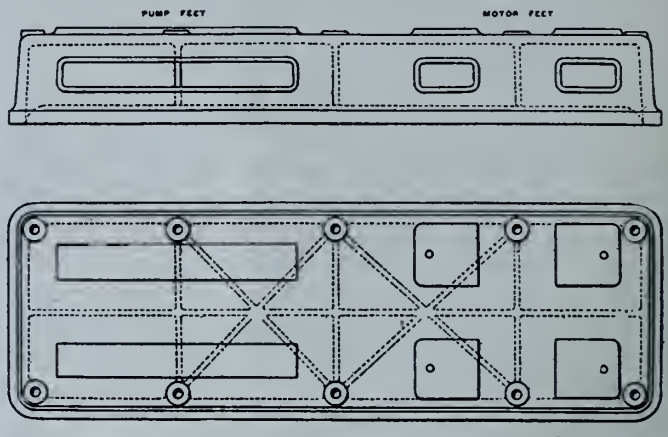

FIG. 33. BEDPLATE FOR "RING" TYPE OF PUMP.

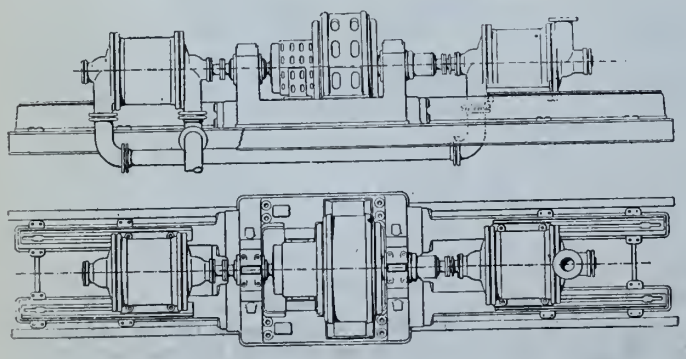

FIG. 32. BED FOR "CYLINDRICAL" TYPE OF CASING.

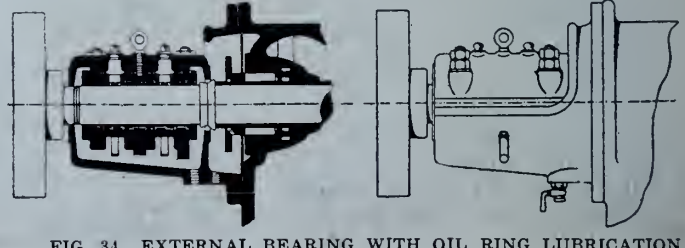

FIG. 34. EXTERNAL BEARING WITH OIL RING LUBRICATION.

consequent upon the increase in diameter of the boss and the neck-rings. It is clear, therefore, that securing the stiffness of a shaft by increasing its diameter is an inefficient method, for, besides the increased area for leakage through the neck-rings, we have much worse conditions of entrance in larger and more rapidly rotating eye and inlet edge of the impeller vanes.

The desirable condition, therefore, from all points of view, is to use the smallest diameter of shaft with the shortest distance between the bearings.

Leakage Between Rotor and Stator

The leakage through the neck-rings may now be considered under different conditions and clearances. The material of these rings is the first important consideration. It is obvious that a material should be adopted in the first place of such a type that it will not tend to drag or tear if accidentally touched or rubbed by the running impeller. Material of a hard "short" nature like cast iron will meet this condition, and in practice the smallest clearance can be successfully run with such neck-rings; they are, however, subject to corrosion, particularly with acid waters, as are frequently met with in mines.

The impeller, for the reason of susceptibility to corrosion, together with considerations of the necessary strength to resist the centrifugal effects of high speeds, is usually made from phosphor-bronze, we therefore frequently get in practice phosphor-bronze impellers running in phosphor-bronze neck-rings, though it is obvious that dissimilar metals would be preferable. A phosphor-bronze impeller with a cast-iron neck-ring is a better combination, and will run with smaller clearances, but to get over the corrodibility of the cast-iron it should be specially treated, or should be similar to that indicated for renewal balancer rings.

Soft metals will not run with fine clearances, for, if any rubbing is set up temporarily or otherwise, through dynamic out-of-balance, or want of alignment from any cause whatever, the metal immediately drags and the pump seizes up. The softer the metal the greater the clearance necessary. White-metal neck-rings have been tried, but were for this reason a failure. Lignum vitae is possible, but owing to its uncertain expansion, a liberal clearance allowance must be made; it provides, however, a material to meet special conditions (mostly stay-bearings in vertical shafts). Lignum vitae is also frequently used in water-turbines, tail-shaft bearings for ship's propellers,

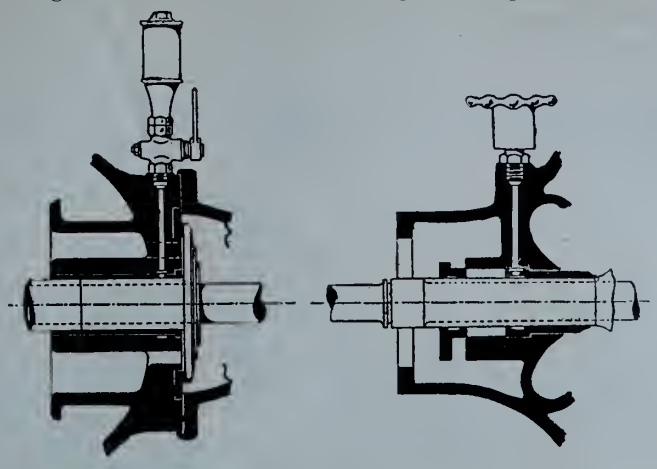

FIG. 35. INTERNAL GREASE-LUBRICATED BEARINGS.

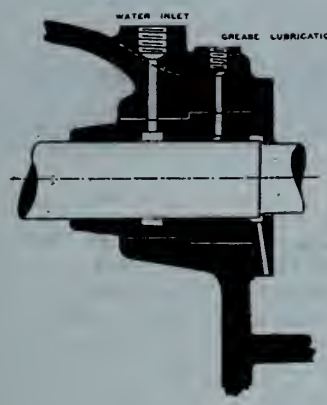

etc. The form of the neck-ring is, in practice, confined to four forms:—

(a)—Internal.
(b)—External.
(c)—Vertical.
(d)—Labyrinth.

Types of which are illustrated in Fig. 31

The first is the usual form in turbine-pumps, the second is more rare, the third is practically restricted to single impeller low-lift centrifugals, while the fourth is a refined form after steam-turbine practice, and is used in some high-lift pumps.

Between (a) and (b) there is little to choose, but for manufacturing reasons, (a) is usually preferred. Clearances of a few thousandths of an inch per side can be run with a suitable shaft, and the leakage is very slight, less than 1 per cent.

(c)—The vertical form is used in pumps for low lifts subject to dirty water and inferior attention. It allows of downward wear of the impeller without any rubbing surface coming in contact with (a) and (b) would not. (d) is an attempt to reduce leakage further by a device of the kind used on the steam-turbine.

For the reason that the labyrinth type deals with a non-expansible fluid like water, and not steam, it is far less effective than in the steam-turbine, and in fact can only restrict leakage by the formation of eddies in the channels or grooves; shock losses at the sudden changes in area and direction, and the centrifugal effect of the rotating film of water in the narrow aperture. Its possible advantages in this way are more than negatived by its fragile nature if it comes in contact with the impeller, such a contingency usually involving the eventual renewal of both parts. Types (a) and (b) only require a new neck-ring for after war. All types, however, are readily made with loose rubbing rings which may be easily changed.

In practice it has been found that when grooves were cut on the impeller-shoulders to secure a labyrinth effect, and at the same time the neck-rings were left plain, that after running for some time the marks of the grooves were always found on the neck-rings; the difference between the worn surface and the original surface often being as much as ten thousandths of an inch, showing in these cases a deflection of the shaft greater than the calculated value. In these particular cases the fact that the grooves appeared all round the ring to the same depth, indicated that they were due to actual deflection and not faulty alignment, the reasons for which may be found in the causes already enumerated and in mechanical inaccuracies.

When interlocking grooves are used, the difficulties of erection and dismantling are increased unless the interlocking is in the plane at right angles to the axis of the pump; any other arrangement is of course only possible with horizontally split pumps or with split or divided neck-rings.

FIG. 36. HAND-OPERATED GREASE LUBRICATOR.

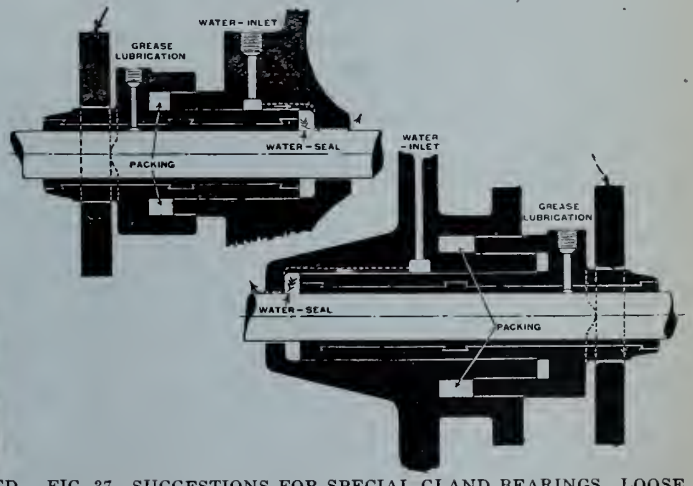

FIG. 37. SUGGESTIONS FOR SPECIAL GLAND BEARINGS. LOOSE FLANGE BEARING ON TWO ROUNDED POINTS ONLY.

V.—The Bed and Other Details

In the past, less importance has been placed in the effect of the bed-plate than is now the case, with the result that fre-

quently very shallow depths were used. These early beds were much too weak to resist warping strains due either to the unevenness of the foundation surface, the "pull" of holding down bolts, or tc the reaction of the torque from the motor-end. It was a common practice to design bed-plates in the form of two separate horns or branches, and in this case deeper sections were generally employed. This form of design while undoubtedly stronger against bending depends too much upon the skill of the plant erector and the solidity of the foundation to always give good results.

It must be obvious that if fine internal clearances, such as have been dealt with, are an advantage, then the common base for the lot—the bed-plate—must be of a nature to ensure the clearance remaining concentric and also to maintain true alignment with the operating motor. For these reasons deeper sections than are usual are an advantage.

With the "ring-type" of casing the bed-plate plays a more important part than with the "cylindrical" type on account of the lesser intrinsic rigidity of the contiguous type and the greater necessity for a plane true surface in erecting; hence the importance of deeper sections becomes more pronounced still. It is now customary to have supporting feet on each "ring" of a multi-chamber pump, probably more for the convenience of re-erection in awkward situations than for any necessity for actual support. Chambers, when dismantling or re-erecting, require to be slipped along the spindle and bed, and for this reason it is usual to machine the latter for its full length.

An example of substantial base-plate provision for a "cylindrical," casing is shown in Fig. 32, and a bed as recommended for a "ring" casing pump is shown diagrammatically in Fig. 33; in cases where there is a heavy torque from the driving motor, diagonal ribs as shown are most valuable in resisting twist on the bed.

Bearings

The almost "standard" speed of 1,450 revolutions per minute for operation of turbine-pumps does not require water-cooled bearings. For outside bearings good design oil-ring lubricated type as shown in Fig. 34 are used, a recommended feature being the provision of a thrower or guard to prevent water from a leaking gland entering the oil well and washing out the oil.

As has already been stated, to keep the distance between shaft supports as short as possible involves the use of internal grease-lubricated bearings, typical designs of which are shown in Fig. 35. This type of bearing, when carefully designed, can be made to operate very satisfactorily in practice despite a contrary view held for some time by some constructors. The important point of arranging for similar hydraulic pressures at each end of an internal grease-lubricated bearing, so as to prevent any risk of flow through the bearing surfaces, must be rigidly followed for best results.

The charging and supplying of grease to internal bearings requires proper lubricators. The ordinary "Stauffer" is unsuitable, though generally a hand-operated appliance of simple design (such as Fig. 36) meets the case; a long trumpet-shaped entrance is essential in order to force against the high pressure due to the head of water against which the pump is working. The selection of a good quality grease lubricant suitable for operating in water plays an important part in the satisfactory lubrication of a bearing.

Stuffing-Boxes

It is doubtful if we can accept the customary stuffing-box and gland as good and satisfactory practice. The functions of ith sdetail are on the suction or vacuum end to prevent air-leakage into the pump, and on the delivery end to prevent pressure leakage from the pump. The action of "packing" on rapidly rotating shafts is so severe as to demand the omission of a stuffing-box wherever possible. On the delivery end of a pump it is easy to avoid a gland either by closing-in the spindle (Figs. 3, 23, and 25), or by so reducing the pressure in passing through an hydraulic balancer that there is no pressure against which to pack (Figs. 4, 12, and 13).

Some constructors have done without stuffing-boxes at both ends of the pump for some time, and they generally rely on pressure water from the pump itself supplying the necessary packing to prevent access of air to the suction inlet. The possibility of difficulty in starting up a pump before the water packing is available should be carefully considered when this method is adopted.

Suggestions for the substitution of a special form of grease-lubricated, gland-bearing without any packing in contact with the rotating spindle, are shown in Fig. 37. Though these bearings are not arranged with end pressure in equilibrium, there is no tendency for water to pass over the bearing surfaces as leakage will take place from the water sealing ring to the reduced pressure of the suction inlet.

BOILER SETTING BRICKWORK

GENERALLY speaking, brickwork will stand without cracks in boiler settings unless it is pushed by the boiler; and it is only necessary to so place it, and have such details about the boiler, that it will not receive any serious pushing. The brickwork should not touch the boiler anywhere, and the space between should be stuffed with asbestos fibre. Although this filling may tend to leak air, the covering over the top of the boiler, which rests on the brickwork, prevents this. The front end of the boiler should be fixed, and the other end should have attached to it some back connection covering which will slide and not tend to push the back wall over.

Boiler Sides Brickwork

The vertical thickness of the brickwork on the sides of the boiler, and almost in contact therewith, should not, says F. W. Dean, be more than 12 in. It has been made 24 in., and in such cases I have seen the part raised bodily, apparently by the expansion of the boiler. This part of the brickwork is usually above the centre of the boiler, but it should be equally above and below the centre as thereby there is less chance of any of its weight being supported at all by the boiler. If the boiler supports it there is a chance that its weight will bend the plates, and the arguments against this have already been given.

It is customary to build the side and back walls of boiler settings with air spaces in order to diminish loss of heat by radiation. That these spaces cause loss of heat by convection and leakage, is probable, and it has been proved by experiments carried out by the United States Bureau of Mines (Bulletin 8) that this is true. If it is advisable to use spaces in the walls in order to prevent cracking of the brickwork, it is best to fill them with some material, such as ashes, crushed brick, sand or other loose material, which will entrap air but diminish its movement. Solid brick walls form a better non-conductor than walls with air spaces.

HIGH VACUUM CONDENSERS

IN purchasing high vacuum condensers, comparison should be made of the pneumatic resistance of the structures on the basis of velocity of flow at each row of tubes and the number of rows in series through which steam must flow. Attention should also be given to possibilities for the formation of air pockets out of the line of flow, considering both transverse and longitudinal sections.

The highest coefficients of heat transmission are obtainable in condensers of moderate size in which the smaller depth of tube bank lessens the pneumatic resistance.

The depression of the air suction temperature below the inlet vacuum temperature is an index of the surface efficiency on the steam side.

By analyzing the temperature depression in a given condenser into that due to pressure drop and that due to partial air pressure, it is possible to determine whether flow conditions or air conditions offer the greater possibility for improving efficiency and vacuum.

By means of accurate electrical resisance thermometers, temperatures can be taken at a multitude of points on both steam and water sides of the surface of a condenser undergoing changes in operating conditions, which would enable one to isolate the factors influencing the extent of the active and inactive zones.

A high velocity of circulating water, or the equivalent increase in water film agitation by the use of cores or spirals, is desirable in the tubes of the active zone of a condenser, and this can be obtained, without additional power consumption in pumping the circulating water, by reducing the velocity of the water through the tubes of the inactive zone.

Power Plant of the CANADIAN KODAK Co. LTD

Mt Dennis, Nr. Toronto, Ont.

STAFF ARTICLE.

Photography has long since been recognized as a public necessity in addition to its practice having become one of our most fascinating and enjoyable pastimes. The manufacture of the wide range of photographic apparatus and supplies with which all of us are more or less intimately acquainted calls for an equally wide and extensive range of high grade factory equipment, and this is specially true of the section of the latter to be found in the power plant department; a pertinent example constitutes the subject matter of this article.

AT Mount Dennis, Ontario, a village situated within a short distance of Toronto, the Canadian Kodak Co. have established their factory and head office. The site and immediately adjacent district are now known as Kodak Heights and from this it may be inferred that the district is high, dry and healthy. It is in many respects an ideal location, being within easy access of Toronto, and having good transportation facilities, also a plentiful supply of water. The site being more or less irregular in contour lends itself to artistic treatment, the grounds have therefore been laid out accordingly. When the trees and shrubs, etc., have grown, it will be, without doubt, one of the most attractive factory establishments in Canada. The site covers twenty-five acres and is located on the Canadian Pacific and Grand Trunk Railways. The main factory and office building stand on the level ground, the power plant being on a slope on the east side. Further along at the bottom of the slope is a reservoir. Provision has been made for future extensions; in addition, a considerable area has been appropriated for recreation grounds, the latter including baseball and football fields, bowling green, and tennis courts.

Building Construction and Layout

The plant is modelled after the Eastman Kodak Co., factory at Rochester, N.Y., being approximately one-tenth the size of that of the parent concern. All the buildings with the exception of the power house, which is of steel frame and brick walls, are constructed of reinforced concrete. Before commencing construction, bearing tests were made of the soil and a safe pressure of one and one-half tons per square foot established. The greatest care was taken during construction in securing only high-class materials, tests being made of the cement and reinforcing steel. Test cylinders were also taken of the concrete from the mixer at regular intervals. Beam girder construction has been employed, with interior partitions of hollow tile and fire walls of brick. Steel sash is used throughout. The roofing consists of 4 inches of cinder covered with cement finish and five-ply tar and slag roofing. Fire escapes are provided as well as stairways of the stair tower type. The main office building contains lunch rooms and is separated entirely from the main factory structure, access, however, can be obtained by means of a tunnel.

BOILER ROOM, SHOWING "BABCOCK & WILCOX" WATER-TUBE BOILERS EQUIPPED WITH "MURPHY" STOKERS

Power Plant Building

The power house is of steel construction with brick walls, and is located in the rear of the main building. It is 235 ft. by 60 ft., and is divided into three sections, containing respectively the engines and generators, refrigerating machinery, and the

EXTERIOR VIEW OF BOILER HOUSE. WATER SOFTENER AND STEEL TRESTLE FOR COAL CARS.

boilers. The boiler room floor is 35 feet below the first floor level of the factory building. In laying out the power plant, provision was made for a 100 per cent. increase in equipment. An advantage is gained by having the boiler room floor on the low level as it allows coal to be brought, from the railways on to a steel trestle, from which it is dumped from the cars into a 600 ton concrete bunker located directly over the boiler furnaces.

Boiler Equipment

The boiler installation consists of four 320 horse power Babcock & Wilcox water-tube boilers of standard construction but with vertical headers. Each boiler has 3014 sq. ft. of heating surface, and carries a working pressure of 125 lbs. per sq. inch. When erecting the boilers, particular attention was paid to laying the fire brick and outside boiler walls. The bricks were dipped in mortar before being laid, thus making practically a brick to brick joint. With this method of construction there is less liability of the boiler walls giving way under the tension of the stoker arches. The boilers are equipped with Murphy automatic, smokeless, mechanical stoker, furnaces, from which the ashes fall directly into a hopper below and are drawn off into small hand cars in the ash tunnel underneath. These hand cars are picked up by a one ton Sprague hoist and deposited in an overhead concrete bin. The chimney is of the radical brick type and is 200 feet high. The boiler feed water is obtained from the reservoir which is fed by three artesian walls. Before being used, the water is passed through a Kennicot water softener which has a capacity of 6,000 U.S. gallons per hour. The boiler feed is taken care of by two 10-6-10 ins. Worthington duplex, outside packed, pot valve, plunger pumps. Before being delivered to the boilers, the feed water is passed through a 1500 horse power heater using exhaust steam at 3 pounds pressure.

The factory is heated by exhaust steam at 3 lbs. pressure. All the steam piping for heating and factory purposes electric light and power conduits, cold water piping, etc., are laid in a concrete tunnel which runs underground from the power house alongside the factory exterior. The tunnels range in size from 9 ft. by 8 ft. to 4 ft 6 in. by 4 ft. 6 ins. Two 10-14-18 ins. Blake-Knowles single vacuum pumps capable of taking care of 80,000 square feet of radiation are installed in connection with the heating system. All the low pressure steam lines are fitted with steam traps.

In the engine room are installed three generating units consisting of a 350 k.w. Corliss engine and Canadian Westinghouse generator; one 150 k.w. Harrisburgh steam engine with generator and a 65 k.w. 14 x 14 in. steam engine built by Goldie & McCulloch, Galt, and direct connected to a Bullock generator running at 235 r.p.m. The first mentioned unit is new while the other two were removed from the old factory on King Street, Toronto. The new unit is an Inglis horizontal, cross compound, heavy duty, Corliss engine having cylinders 18 in. and 30 in. by 30 in. stroke, running at 150 r.p.m. It is direct connected to a 300 k.w. Canadian Westinghouse 3-wire, 125-250 volt, d.c. compound wound commutating pole type generator. The engine operates on a steam pressure of 150 pounds with 5 pounds back pressure. The valve gear is operated by double wrist plates set for long range cut-off, the governor controlling both high and low pressure cylinders. The fly wheel is 11 feet diameter and weighs 22,000 pounds.

The switchboard which was supplied by the Canadian Westinghouse Co. has

150 K.W. "HARRISBURG," AND 65 K.W. "IDEAL" ENGINES, WITH ALLIS-CHALMERS-BULLOCK GENERATORS.

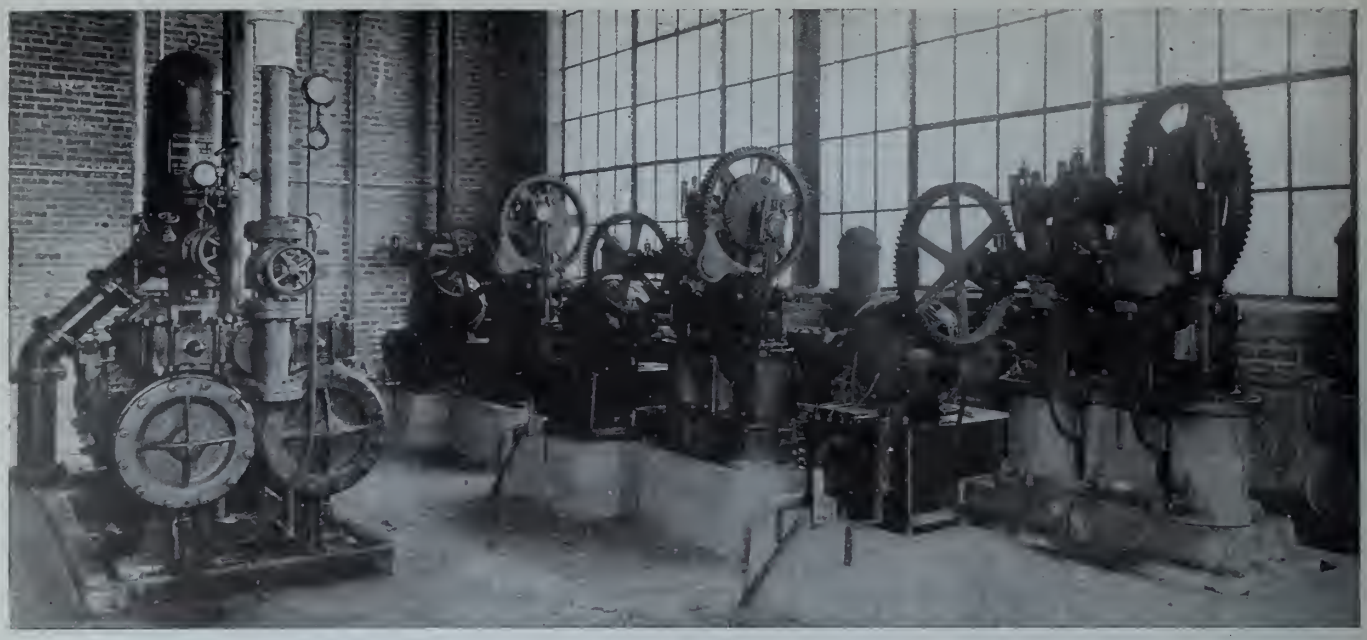
six black marine finish slate panels, 90 ins. high and 24 ins. wide. Each panel is divided into three sections, the top slab being 20 ins., the middle, 45 ins.; and the bottom slab, 25 ins. deep. The first panel controls the 62 k.w. generator; the second panel, the 150 k.w. generator; while the third panel controls the 300 k.w. unit. The fourth, fifth and sixth are feeder panels. Each feeder is supplied with a pair of carbon circuit breakers and a Sangamo watt-hour meter. There are two volt meters on a swinging bracket at the end of the switchboard. All cables have flame-proof insulation and are run from terminals at the bottom of each panel down through a slot in the floor. They are supported by porcelain clamp insulators between there and the generators. Cleats are fastened on underside of floor between the switchboard and generators. The feeder cables are carried in the same way through the tunnel between the power plant and factory already referred to. In the factory there are approximately 148 Fairbanks electric motors of 230 volts, d.c., ranging from ¾ to 25 horse power.

The refrigerating system is an important feature at the Canadian Kodak Co. factory, the new unit about to be described being the largest single acting ammonia compressor installed in this country. The total capacity of the refrigeration plant is 390 tons, the main unit being a 200 ton vertical ammonia machine consisting of two vertical, single acting compressors, each 21 in. bore by 32 ins. stroke, and equipped with safety heads. The discharge end of the compressors is water-jacketed, and the suction end insulated with "'nonpareil" cork. Each compressor is equipped with indicator connections and pressure relief valves in heads, while the stuffing box nuts are operated by hand wheels geared from same, so that they can be adjusted by the engineer standing on the floor. Each compressor is direct-connected to a horizontal cross—compound Corliss engine, the high pressure cylinder of which is 20 in. by 32 in., and the low pressure 38 in. by 32 in. Each steam cylinder is equipped with force feed lubricator, hand oil pump, indicator connections, and two relief valves. The piston rods are of nickel steel. The pistons have metal wearing rings in addition to the packing rings. Each machine is packed throughout with metallic packing, in addition it is fully equipped with the requisite accessories, including nickel-plated revolution counter with 10 in. dial, and a central oiling system. The compressors have a capacity of 200 tons of refrigeration in twenty-four hours when operating at 185 pounds condensing pressure, 20 pounds suction pressure, and 65 r.p.m.

GENERAL VIEW OF "KODAK" PLANT FROM THE WEST. FACTORY BUILDINGS ON LEFT, MAIN OFFICE BUILDING ON THE RIGHT, AND POWER HOUSE BEYOND.

The compression side consists of eight of the latest type double pipe, flooded ammonia Shipley condensers, made up of 2 in. and 3 in. piping, 18 feet long. These condensers are equipped with a purge drum for collecting the foreign gases, and have washout connections for the water tubes in addition to the regular water and ammonia valves and connections. The ammonia receiver is 3 feet 6 in. in diameter and 16 feet long, and the high pressure oil separator is 2 feet in diameter and 8 feet long. Both are wrought iron welded shells of standard construction. A check valve is located in the 5-inch discharge line between the compressor and the condenser. The evaporation side of the plant consists of water coolers and brine coolers, located in the room adjacent to the engine room, from which the water and brine are pumped to the different points

GENERAL VIEW OF ENGINE ROOM, SHOWING 300 K.W. "INGLIS" CORLISS ENGINE, AND CANADIAN WESTINGHOUSE GENERATOR IN FOREGROUND; "HARRISBURG" AND "IDEAL" ENGINES AT REAR.

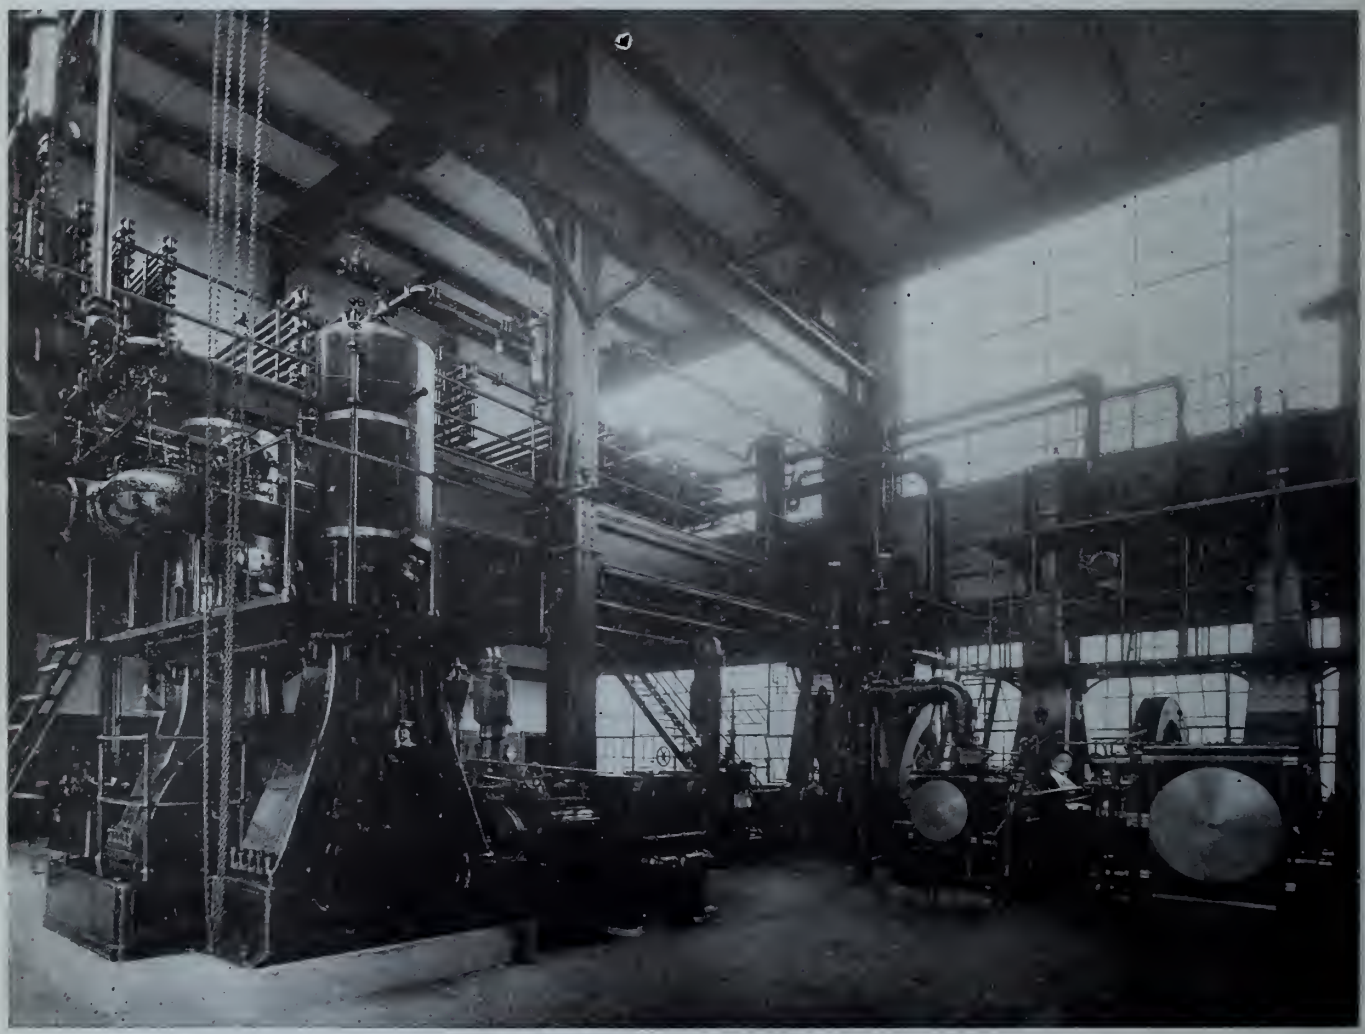


PART OF PUMPING INSTALLATION WHICH COMPRISES A CANADA FOUNDRY CO. "UNDERWRITER" FIRE PUMP; TWO "GOULDS" 3" x 10" TRIPLEX, COLD WATER CIRCULATING PUMPS, AND ONE "GOULDS" 10" x 15" TRIPLEX, BRINE PUMPS.

in the factory where the refrigeration is required.

Water Cooling

Water cooling is accomplished by means of twelve stacks of water cooling coils, arranged in two batteries of six stacks each. Each stack is made of 2 ins. galvanized ammonia pipe, twelve pipes high and 20 feet long, equipped with water distributing trough and galvanized iron splash strips between each pipe. Each battery of water coolers is equipped with oil drains and collecting tank, and the suction gas passes through a trap or accumulator which separates



REFRIGERATING PLANT, SHOWING 65-TON "YORK" COMPRESSOR ON LEFT; 125-TON "DE LA VERGNE" MACHINE WITH "YORK" COMPRESSOR IN CENTRE, AND 200-TON "YORK" MACHINE ON RIGHT. SHIPLEY CONDENSERS ARE ON MEZZANINE FLOOR ABOVE.

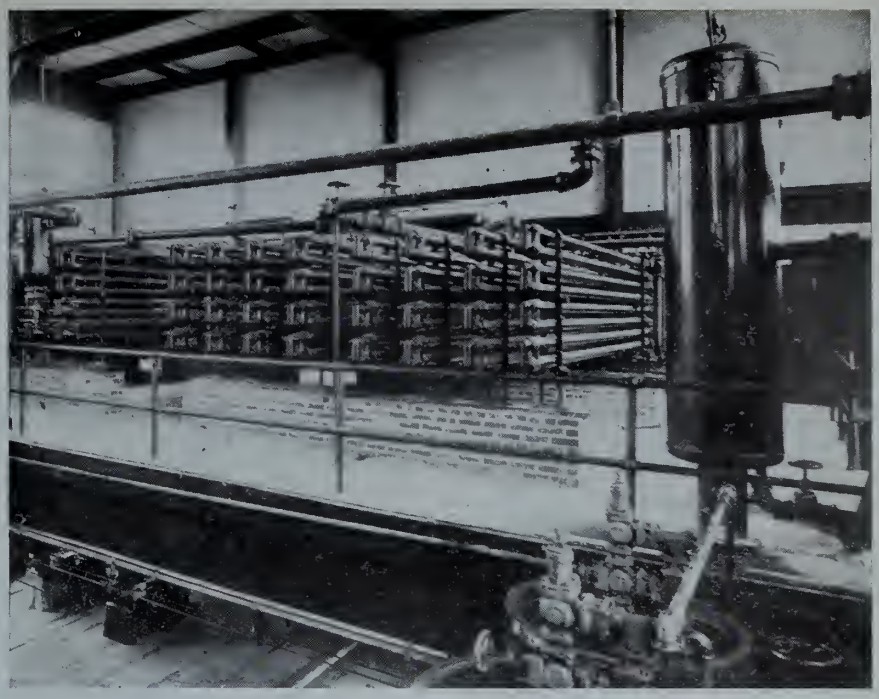
any liquid ammonia before it passes on through the main 30 ins. by 10 ft. scale trap in the suction ammonia line near the machine. By means of these various traps, the gas is bound to reach the ammonia compressors in a slightly superheated condition—which insures the machine operating at the very highest efficiency, at the same time enabling the cooling coils to be flooded with ammonia so that they also work at their maximum efficiency.

Brine Cooling

The brine cooling is accomplished by means of two York shell and tube type horizontal brine coolers, one 51 ins. in diameter by 16 feet long, the other 39 ins. by 12 feet long, with location provision for future coolers on the floor above the water cooling room.

The brine storage tank has a capacity of thirty thousand gallons, and is located on the floor above the brine coolers. Two 500 gallons per minute brine circulating pumps are located in the basement three floors below the brine tank, and one floor below the machine room. Eight-inch brine mains connect them to storage bank, brine cooler and cooling system.

The water cooler room, brine cooler, brine tank, brine mains, and all exposed cold ammonia mains are insulated with 'nonpareil" cork. The cold water circulating pumps and brine pumps are of the triplex type, each pump being direct connected to its own motor. The water for ammonia condensing purposes is cooled by means of an atmospheric type water-cooling tower on the roof of the main building. The water is circulated over this tower through the condensers by means of two Goulds centrifugal pumps direct connected to motors, each having a capacity of 500 gallons per minute.

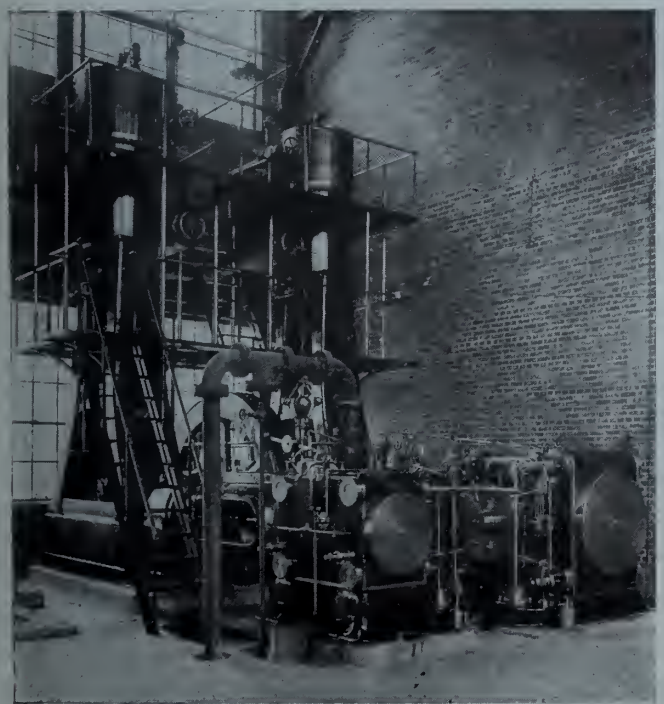


"SHIPLEY" DOUBLE PIPE FLOODED CONDENSERS ON MEZZANINE GALLERY.

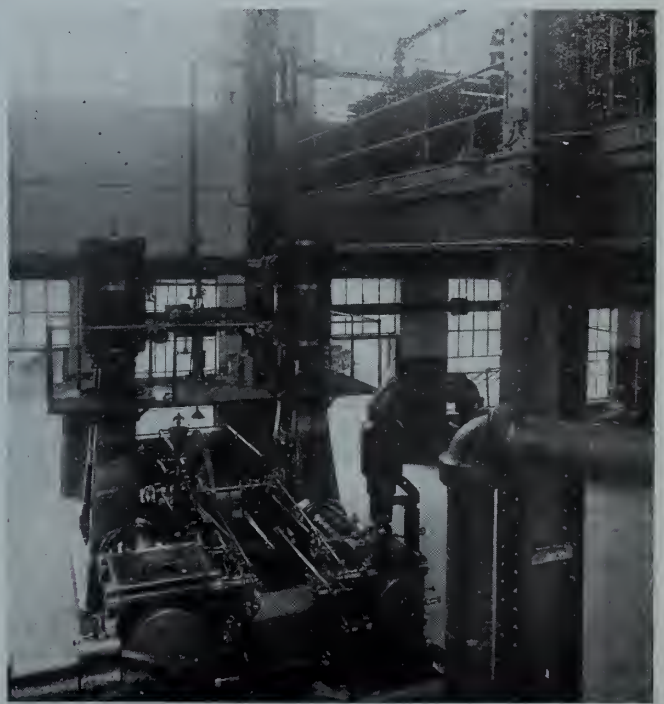
In addition to the new equipment described, there is a York 14 by 21 ins. vertical, single-acting compressor, direct connected to a 14 by 26 by 21 ins., cross compound, Corliss engine, and a vertical De La Vergne machine equipped with York 18 by 28 inch ammonia compressor of 125 tons capacity. This machine is direct connected to a horizontal simple Corliss engine. These units were moved from the old plant. The compression side for these two latter consists of eight stacks of standard counter current double pipe ammonia condensers, and five stacks of flooded double pipe ammonia condensers, with all necessary high pressure traps, receivers, etc. These are cross connected to the new unit and are arranged so that any one machine can be used on any or all of the condensers, either together or separately.

General

Two Northern hand operated cranes are installed, one in the engine room having a capacity of 15 tons, and a span of 49 ft. 3⅛ ins., while the other crane in the compressor room has a capacity of 15 tons and a 27 ft. 8 ins. span. Both cranes are rope drum, hand power type, designed for power station service, and are operated from the floor. The hoist



200-TON "YORK" VERTICAL, SINGLE-ACTING REFRIGERATING MACHINE, COMPRESSOR CYLINDERS, 21 INS. DIAMETER BY 32 INS. STROKE.



65-TON "YORK" VERTICAL, SINGLE-ACTING REFRIGERATING MACHINE. COMPRESSOR CYLINDERS 14 INS. DIAMETER BY 21 INS. STROKE.

has two speeds, the bridge and trolley, both being geared for travel by hand chains. The gearing is all of cut type, and the axles are fitted with roller bearings.

All the brine and chill water lines are carried from the power house to the various buildings through the underground tunnels already described. An 80,000 gallon closed-in concrete reservoir has ben constructed for providing pure water for drinking and factory purposes. The reservoir is supplied from three artesian wells as already stated. The overflow from this reservoir goes into a 75,000 gallon open concrete reservoir which supplies the boilers. A 25,000 gallon steel tank supplies water for general factory purposes.

BRUSH-HOLDERS FOR SLIP RINGS

BRUSH-HOLDERS for metal graphite brushes take forms both foreign and akin to direct-current holders. With these holders the brushes require the usual multiplicity of expensive shunts, the necessity for which, with a proper holder, is at least debatable. Inasmuch as slip ring brushes may be placed indiscriminately around the rings, there is no occasion for maintaining a fixed brush relation to the rings. The ideal holder, therefore, may be in the development of the swivel type, in which the brush may be clamped in the box and the brush itself requires no shunt. The box should, however, be heavily shunted to the holder support in order to protect the swivel from possible arcing due to the current passing through the swivel joints. The brush will require occasional readjusting in the holder due to the wear of the brush reaching, from time to time, the travel limit of swivel. (This limit should not permit the holder to come in contact with the ring). This requirement, however, will not approach the work involved in trimming copper leaf brushes, or in cleaning the accumulated dust from between the brushes and holders, as is necessary with present holders.

At the present time a few slip ring motors are being fitted with a holder of the foregoing type, but the value of its general application has not been fully determined. Present holders are designed to take single brushes, or two brushes side by side, or two brushes in "tandem." The last-named holder is the least desirable for the reason previously stated. However, it has the advantage of economizing the space around the ring and to a degree precluding congestion. Its single objection can be readily overcome by using a partition between the brushes.—Electric Journal.

HANDY CHART FOR ESTIMATING PULLEYS, FLYWHEELS, ETC.

By "Woodworker."

HERE is a chart that will come in handy in a number of ways wherever circular motion is to be computed or estimated. Knowing any two of the factors shown in columns A or B, the third can be found.

For example, a 20-inch pulley makes 600 revolutions per minute. What is the speed of the pulley periphery in feet per minute? This is a very common problem.

Find the 20 (column B) and the 600 (also in column B), and then locate the point half-way between them. This is done by folding a strip of paper, by means of a pair of dividers, with a ruler, etc. There are many good ways in which to find a mid-point. Directly opposite that mid-point is the answer—very close to 3,200 feet per minute.

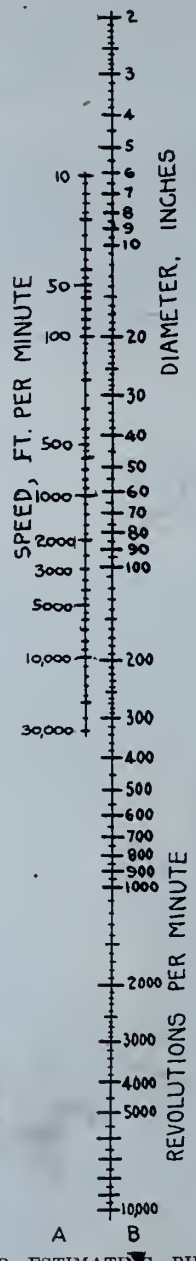


CHART FOR ESTIMATING PULLEYS, FLYWHEELS, ETC.

This answer is not exact, of course, nor does a slide rule give an absolutely accurate answer, but it is close enough for most practical purposes. The designer is generally most anxious to keep well within the bounds of safety. Well, 3,200 ft. per minute is a safe speed for almost any pulley. In fact, a mile a minute is usually given as the maximum speed for wood pulleys, cast iron pulleys, and others of a brittle nature. Steel pulleys are often allowed to run at 6,000 to 7,000 ft. per minute, and in extreme cases even that speed has been beaten, but nobody should ever attempt a greater speed than a mile a minute without being absolutely sure of himself, his calculations, his design, etc. It has often been pointed out that the energy stored in a flywheel sometimes reaches stupendous proportions and when a flywheel explodes we all know the attendant results.

Again, when it is desired to determine the approximate number of revolutions per minute at which a given pulley will run when the diameter and belt speed are known, the chart is used in this way:

Take the same example as above. Let us assume that the diameter of the pulley is 20 inches and the speed of the belt 3,200 ft. per minute. What will be the r.p.m.?

Find the distance between the 20 (column B) and the 3,200 (column A), and measure that self-same distance downward from the 3,200, and there's the answer in column B = 600 r.p.m. This method is just the inverse of the first, of course.

Lastly, if the speed in feet per minute is known and if the r.p.m are known, the diameter in inches of the required pulley is found by following the same tactics as in the last example. Using 600 and 3,200 as known quantities, the answer will be found to be 20 inches.

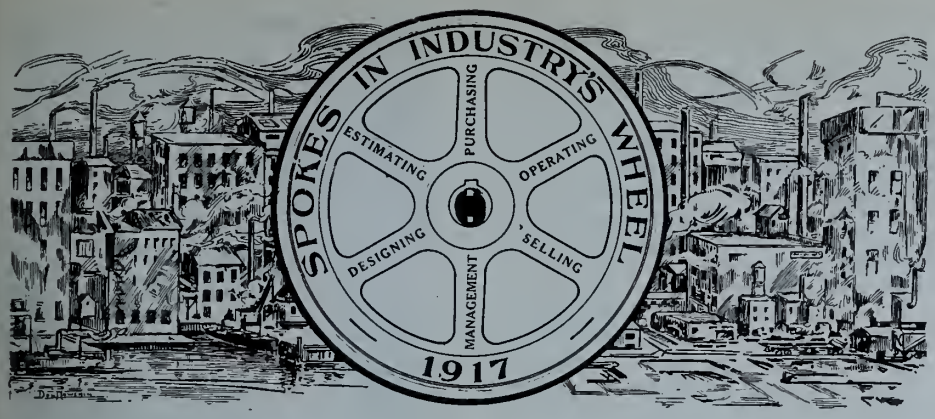
In metal turning, also, this chart will be found useful for determining cutting speeds. Knowing the diameter of the stock and the r.p.m., the cutting speed is found as in the first problem cited here. If the diameter is 1 inch, use the 10 on the chart and mentally divide the answer by 10. If the diameter is 1.5 inches, use the 15-inch mark, and again mentally divide the answer by 10. It is thus evident that the range of the chart is virtually unlimited.

ADDITIONAL AIR OVER FUEL BED

ADMISSION of air into the boiler furnace through leaks in the furnace wall is undesirable and should be avoided.

The ideal way to supply additional air over the fuel bed is to introduce it as close to the latter and in as large a number of small streams as possible. The nearer the air is introduced to the surface of the fuel bed, the more combustion space is utilized for mixing air with the combustible gases and for burning the mixture. A large number of small streams of air entering the furnace facilitates mixing the air with the combustible gases, particularly if it is forced in at high velocity. When the air is introduced in one large stream at low velocity it tends to flow parallel to the stream of combustible gases without mixing with them, thus causing slow combustion. The rate of mixing determines the rapidity of combustion of the combustible gases. With a perfect mixture and the usual furnace temperature, the velocity of combustion is very great indeed, so that the combustion is almost of the nature of an explosion.

From Technical Paper 137, U.S. Department of the Interior.



The constitution of industrial enterprise is largely departmental—"Spokes in a Wheel." This series has for its object the featuring of, in racy, interesting and instructive fashion, the training, experience and achievement of those who to-day are transmitting effectively, energy in a variety capacity as "Spokes in the Wheels" of steam, electrical and hydraulic and refrigeration engineering.

WILLIAM A. SWEET

THE development and transmission of electrical power has advanced to such a point, and demands such qualifications in the individual that it may well be said that wires like guns need men behind them. Electrical engineering in its operative features, requires a degree of practical experience equalled only by mechanical engineering, and obtainable only by lapse of time and occurrence of trouble. Just as it is impossible to cross bridges before you come to them, so is it impossible to gauge one's ability to overcome trouble until unwelcome events have presented themselves for solution. While it is not implied that the subject of these remarks has a special leaning toward trouble, it is believed that, because of the closeness with which his personal career and activity are interwoven with the development of his present duties, his biographical details possess more than passing interest for readers of this journal.

The early days of electrical engineering were characterized by a rapidity of development experienced by few other industries and the fact that our "Spoke's" experience with electrical machinery dates from the early "Eighties" is sufficient evidence that he not only knows how to meet trouble when it comes but what is perhaps more important, is capable of maintaining a preventive attitude against the trials and sorrows of the station engineer.

Born in the county of Wentworth, township of Salt Fleet, May 3, 1862, William A. Sweet is a Canadian son of Canadian parents, although four generations back his forefathers were of Holland birth. After receiving the ordinary school education of that period, he commenced work at the age of sixteen, learning the milling trade in the town of Woodburn, Ont., where he was employed at the Woodburn Flour Mills. They were owned by John Edmonds and during the three and a half years he was there, Mr. Sweet had charge of a beam engine having a cylinder 20 in. dia. by 5 ft. stroke, running at 30 revs. per min. An interesting feature of this plant was the presence of a water tube boiler of which the following description is given: A main horizontal shell about 6 ft. dia., and proportionate length, had a central rectangular flue 48 in. wide by 30 in. high. About 500 tubes were disposed vertically in this flue, connecting the water

W. A. SWEET.

spaces above and below the square flue. This boiler was made by some firm in Hamilton, whose name history recordeth not.

After a short time with Morgan Bros., who owned a flour mill in Hamilton, Mr. Sweet decided to become a real out and out engineer, and with this end in view he commenced his apprenticeship in 1882 with the firm of Reid & Barr, who were engaged in the building of stationary and portable engines and also boilers. The four years spent there were full of opportunity, particularly as regards the operation of machinery, a fact which was to be of considerable influence in the later activities of our friend.

At this time, Mr. Sweet devoted considerable time to study, taking both the electrical and steam engineering courses of the Scranton School, so that he was amply qualified to take charge of the electrical plant at the Royal Distillery, Hamilton. This equipment included one bi-polar dynamo of 400 light capacity, 2 bi-polar motors and one electric lift. Three boilers of 125 horse-power were installed, and the engines were one 100 horse-power, and one 20 horse-power, the latter being an Armington & Simms, built by the Inglis Co., of Toronto. The electrical machinery was built by Tom Kay, of Hamilton.

Mr. Sweet's connection with the various plants now owned by the Dominion Power & Transmission Co., dates from June 1, 1894, when he took charge of the power plant of the Hamilton, Grimsby and Beamsville Electric Railway, this plant being under his care till the present time. His duties were extended in Sept., 1896, to include the power plant of the Hamilton Radial Electric Railway, this latter plant being in continuous operation as a generating plant until 1901, when it was converted to a transformer and motor-generator station. At this time Mr. Sweet was placed in charge of all stations owned by the Hamilton Cataract Power, Light and Traction Co., these consisting of the old electric light plant on King street, the Street Railway plant at the foot of John street, and the Grimsby Electric plant.

The formation of the Dominion Power and Transmission Co., solidified the various electric projects in the Hamilton district and incidentally increased Mr. Sweet's responsibilities so that in addition to the companies mentioned he has charge of plants belonging to Hamilton & Dundas Street Railway, Dundas Electric Co., Brantford & Hamilton Elec. Ry., Hamilton Terminal Co., and Western Counties Electric Co. The Victoria Ave. sub-station belonging to the old Cataract Co., is the only plant where steam generation is still in use.

Social and political activities of limited degree have characterized Mr. Sweet's past life. Radical in politics and Anglican in religion, he has never been attracted by municipal politics. A Mason and member of the I.O.O.F., he is also a member of the C.A.S.E., being one of the old members of No. 2 Lodge, past president of the C.A.S.E. executive, and a warm friend of that organization.

Hunting is his chief relaxation, and a fall trip has been an annual feature for the last 25 years.

On Jan. 26, 1889, he married Cozens Tryphena, of Hamilton, the union being

blessed with two sons and two daughters, one of each of whom is married; the family residence being 78 Colborne St., Hamilton, Ont.

Outside of his duties, Mr. Sweet has various interests, one of special interest at this time being the Hamilton Molybdenum Alloys Co., of which he is a director. His success in life he attributes to a lot of mighty hard work, not a little of it being study in the wee sma' hours of the morning; in fact, he admits that his wife has occasionally hidden books from him for days at a time. She cannot, however, deprive him of technical papers, which appear regularly, and Mr. Sweet regards these as one of the necessities of life for the modern aspirant to success.

Cool collectedness is particularly necessary for successful electric station operation and both Mr. Sweet's personality and the various plants under his control bear out the truth of this assertion.

BRUSHES FOR SLIP RINGS

THE copper leaf brush for slip rings. which has been in favor since the days of incipient machines, is fast giving way to "block" or "metal graphite" brushes. Generally speaking, metal graphite brushes consist of various mixings of pulverized copper and other metals with graphite, shaped under pressure. When metal graphite brushes were first introduced their carrying capacities were greatly over-estimated. Manufacturers of electrical apparatus dropped into the error of using too few brushes, and in many instances found it necessary to increase the slip ring brush equipment as much as 50 per cent. before satisfactory results could be obtained in the field. At the present time the maximum permissible current is considerably below 150 amperes per square inch, while the safe limit is perhaps under 125 amperes per square inch. This type of brush is also used on direct-current machines of very low voltages. Its metallic characteristics, however, are at times hard on the commutators.

As a rule, the more highly graphitized brushes have proven the more satisfactory in that they have a longer life and cut the rings less. It is contended that these brushes are self-lubricating, and to a degree this is true. However, if the rings on which they run are kept free from copper dust, and a slight amount of lubrication (light oil) is judiciously applied, the life of both brushes and rings will in most cases be prolonged. This type of brush is extremely heavy and requires a brushholder of decided stability, with springs capable of pressures as high as five or more pounds per square inch. The actual pressure to be used is determined by the type of ring, speed of ring, and composition of the brush. It is, however, rarely less than three and one-half pounds per square inch, and more frequently five. When brushes of this type are allowed to spark they disintegrate rapidly and the life is greatly shortened.

In case the brush is not sufficiently granular in texture it will "roll up" or "fringe" or form "wire edges" on the sides. Obviously, such brushes are dangerous, for the reason that such edges frequently break away from the brush in full contact length, bridge to, or fall across, rings having different polarities, and flash the machine. To guard against this the brush should be slotted radially with a file, two slots to a side "V" shaped, and about one-eighth of an inch in depth. Under this condition the maximum possible length of thrown-off metal will be something less than one-third of the arc of the brush contact. This is too short to bridge or cause damage. Although a brush may be in every other way satisfactory, if it has this "fringing" characteristic it is not desirable.

Application of Slip Ring Brushes

All types of slip ring brushes should be installed so as to cover the full width of the ring, but never so as to permit the brush to overhang the ring. This is easily accomplished by properly "staggering" the brushes, all slip ring brushholders being designed for this adjustment. Metal graphite or "block" brushes are generally installed radially, and with either one or two brushes in each holder. When two brushes occupy the same holder they should be placed side by side —not in "tandem." If in "tandem," the leading brush is packed against the leading face of the holder by the lagging brush, due to the rotation resultant, and the brushes do not wear uniformly. It may be possible to overcome this by changing the brush angle, or by a change in the resultants of spring pressures. As previously stated, the pressure should be from three to five pounds per square inch.

A Rope Drive Puzzle.—In connection with rope driving the question is sometimes asked: "Why do some ropes revolve in the groove, while others do not?" In a paper on "Rope Driving," read recently by R. Edward Hart before the members of the Bradford Engineering Society, the author says this question has never been satisfactorily answered. It is reassuring, however, to learn from the paper that whether ropes revolve or not has very little to do with their longevity, as it is easy to point to both types which have worked well for many years. Some people, says the author, imagine that when a rope begins to revolve it is rapidly rubbing itself away; this is quite an erroneous view of things. As a matter of experience, the ropes which have the longest life are, in the majority of cases, quite circular in section. And when the ropes have been running for any length of time, it is always easier to tighten a round rope which has been worn evenly all over its surface than to attempt to resplice a rope which has worn V-shaped and taken all the wear on its two sides only. Some engineers prefer ropes to revolve, because they affirm that there is less frictional loss whilst leaving the groove with a round rope than with a V-shaped rope, maintaining that it partakes more of the nature of rolling friction.

ORDERING COMMUTATOR BRUSHES UNLESS the style, type, size and shunt equipment of a brush can be definitely given when brushes are ordered, the folfollowing information should be furnished the brushmaker, or the manufacturer of the machine, when an order for brushes is placed:—

1—Size of brush, in the following order:—Length, width, thickness.

2—Bare or copper-coated.

3—Brush angle; also if corners are square or chamfered.

4—State whether rotation is against toe or heel of brush.

5—If to be drilled for shunts, or countersunk, or both, give full particulars.

6—If to be equipped with brush-lifting devices, give full particulars.

7—State whether for one, two or more shunts, giving length of flexibles and styles of flexible terminals.

8—Specify if shunts or brush-lifting devices, or both, are to be either attached or supplied.

9—Give all information on the nameplate of the machine.

10—Give diameter of commutator (or rings).

11—State whether or not mica is undercut.

12—Give maximum number of bars touched by the brushes.

13—Give number of segments between centre of positive and centre of negative brushes.

14—Give number of poles (or brush arms) and number of brushes per arm.

15—State if machine is of commutating-pole or non-commutating-pole type.

16—Give style or type of holder.

17—If brushes in use have not proven satisfactory, state in what respect they have failed.

18—If convenient, forward a used sample of the brushes in service. It frequently happens that a more suitable brush can be prescribed and that an examination of the original brush will not only suggest a substitute having superior characteristics, but at the same time eliminate possible errors in brush dimensions, shunt applications and brush-lifting mountings.

19—Bear in mind that brushholders differ greatly in detail and that the application of shunts for either direct or alternating-current service must be specified; otherwise the shunts might interfere with the pressure springs and a set of brushes be rendered useless.

20—It is also well to furnish a sketch of the brush.

21—If for "try-out" purposes, state what service the machine is doing; hours of service; minimum, average and maximum loads, with duration of each; also if machine is subjected to gas or acid fumes, and what, if any, troubles have been experienced.

From the above it must be concluded that if what is wanted is expected it must be made clear what is wanted. Even then it may not be available. Brush requirements are in no sense stable. It is wise, therefore, to encourage a receptive disposition and to be ready for such advances in the art as may seem worth while.—Electric Journal.

Sub-Station Equipped With Auxiliary Steam Plant

Staff Article

The merits of a steam plant—elasticity, emergency availability and generally speaking, all-round reliability, insure a continuance of such equipment, principally as reserve power in many electric systems. DeCew Falls, illustrated herewith, possess the unique feature of having been the original inspiration of the now important electric system which covers such an important part of the Niagara Peninsula.

DECEW FALLS.

NOTWITHSTANDING the high degree of perfection attained in the development of hydro-electric systems, the necessity of a steam plant, either as an auxiliary or reserve, or both, is recognized to a considerable degree by many operators who control public service plants, and the Victoria Avenue substation of the Dominion Power & Transmission Co., Hamilton, Ont., is an interesting example of equipment, which, while primarily designed for auxiliary purposes, possesses a sufficient overload capacity to enable it to act as reserve to quite a considerable degree in the case of sudden emergency.

The sub-station itself possesses considerable interest in that it was erected by the old Hamilton Cataract Power, Light & Traction Co., which was subsequently absorbed by the Dominion Power & Transmission Co., which now controls and operates numerous subsidiary companies in the Hamilton district.

VIEW OF OFFICES AND MAIN ENTRANCE, VICTORIA AVENUE SUB-STATION.

Main Power Station

The hydraulic power plant is located near DeCew Falls, a short distance from St. Catharines, and 34 miles distant from Hamilton. The effective head obtained is 265 ft., almost the entire difference in level between Lake Erie and Lake Ontario, and the highest head of any of the power plants in the Niagara peninsula. When first erected in 1897, the plant consisted of one penstock and two hydraulic units with an output of 3,000 units. To-day there are seven penstocks, each 750 ft. long by 6 ft. dia., supplying power to electrical units of about 7,000 horse-power each, and giving a total output for the plant of 52,000 horse-power.

DECEW FALLS POWER PLANT OF THE DOMINION POWER AND TRANSMISSION CO.

The gate-house, penstocks, and power house are illustrated in one of the accompanying engravings, as is also DeCew Falls, which give their name to the locality, and suggested the title of the old Cataract Co.

Main Line Transmission

There are three separate main lines, which transmit the power from the Falls to Hamilton at 44,000 volts, terminating at the switching station at the eastern extremity of the city, this station being entirely out of doors and the first of its kind in America. From the switching station three lines enter the city of Hamilton, two run to Brantford, a distance

of 23 miles, and one runs to the Beach, Burlington, and Oakville, a distance of 22 miles. The various districts are provided with sub-stations for transforming the voltage to suit local requirements and two of these stations—Victoria Ave. and Cannon St., have motor-generator sets installed which supply direct current to the Hamilton Street Railway Co. The transformer capacity of the Cannon St. sub-station is 8,000 k.w., while the sub-station at Irondale, East Hamilton, has a transformer capacity of 7,000 k.w., no motor-generators being installed here.

Plant at Victoria Avenue

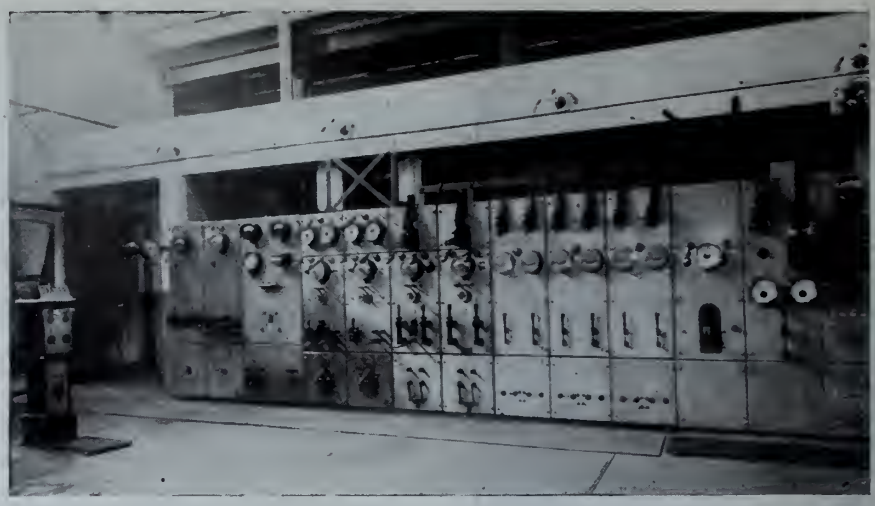
The Victoria Ave. sub-station which is illustrated in the accompanying engravings is of similar transformer capacity to the Cannon St. sub-station, but with the added capacity of the auxiliary steam plant which is the principal feature of the installation.

BATTERY OF OIL SWITCHES BETWEEN LIGHTNING ARRESTERS AND TRANSFORMER ROOM.

The transmission line from the switching station enters at the south or rear side of the building (see illustration), this being 3-phase, 2,400 volt, a.c. current. The lightning arresters are located outside in the open, from which the lines pass into the switch room. The interior of this room is shown in one illustration, the oil switches being installed in front of a brick wall which forms one end of the transformer room.

Transformer Room

The transformer room occupies most of the west side of the building and contains 16, 500-k.w. units arranged in two banks of 8 each. Situation between the banks is a brick wall of cellular construction, extending up to the roof. As shown in illustration of transformer room, the wall is divided into three square conduits or passage by means of concrete slab divisions which both insulate and protect the three-phase conductors coming from the switch room. The transformers are of Canadian Westinghouse make and deliver two-phase current at 2,400 volts. The illustration shows clearly the arrangement of the transformer room and the connections from each unit to the three-phase conductors located in the conduits referred to.



SWITCHBOARD FOR STREET RAILWAY MOTOR GENERATORS. CONCRETE CONDUIT FOR MAINS OVERHEAD. MAINS RISE IN CONCRETE COLUMN BACK OF LATTICE WORK.

Motor-Generator Department

The two-phase current from the transformers is led by underground conductors to the motor-generator department, which occupies about one-third of the building from front to back. The switchboard equipment is arranged around two sides of this department, the west side being occupied almost entirely by the railway board in connection with the motor-generators, while the north side is occupied by the high tension lighting load board and local power panels.

The railway switchboard, a photograph of which is reproduced, consists of 13 gray marble panels, the extreme right hand panel carrying the return mains and also the sectional switches for the railway. Automatic switches in connection with the booster equipment occupy the adjacent panel, while the remaining panels are equipped with standard types of instruments and apparatus for controlling the supply of alternating current to, and delivery of direct current from the two motor-generator sets.

These sets are installed exclusively for supplying 600 volt direct current to the street railway and are of identical size and type. They are of Canadian Westinghouse manufacture and consist of a 1,330 horse-power synchronous motor, operating with the two-phase, 2,400 volt current at a speed of 333 revs. per min., and direct-connected to a direct current generator of 750 k.w. capacity delivering 1,250 amperes of current to the railway switchboard at an E.M.F. of 600 volts. The armature shaft extends

END VIEW OF TRANSFORMER ROOM SHOWING CELLULAR CONSTRUCTION OF CONDUIT WALL.

out from the generator and embraces the exciter unit which is mounted at the end of the bed plate. This unit is of 50 k.w. capacity, delivering 400 amperes at an E.M.F. of 125 volts.

Booster Equipment

The booster set for the motor-generators consists of a 170 horse-power Canadian Westinghouse constant speed induction motor operating with two-phase, 2,400 volt current at a full load speed of 645 revs. per min., direct-connected to a 112½ K.W.d.c. generator having an output of 1,500 amperes at 75 volts. The remainder of the apparatus in the motor-generator department includes an independent motor driven exciting set of 50 K.W. capacity, consisting of a Bliss non-condensing steam turbine operating at 160 lbs. per sq. in. and a Diehl generator delivering 125 volt current, speed of set being 2,000 revs. per min.

Reference was made to the switchboard on the north side of the building, and this can be seen in the view of the motor generator department. The mains from the transformers rise through a vertical concrete column to the top of the railway switchboard from whence a conduit extends horizontally around the two sides of the department directly above the switchboard. The switchboard referred to is of comparatively simple construction of 18 panels arranged for individual lighting and power loads for various concerns in the vicinity. These operate on the two-phase, 2,400 volt current direct from the transformers, and are divided equally between lighting and power. A 15 ton overhead traveling crane built by Pawling and Harnischfieger, provides lifting capacity in any part of the motor-generator room.

Steam-Generator Department

The auxiliary steam plant is of more than passing interest to Canadian power house operators, being excellent examples of modern high class engine design and possessing special operating features which, while remarkable enough at the time of their installation in 1903, are still little if any surpassed by similar units as built to-day. These sets are the subject of one of the illustrations, while they can also be observed in the background of the view of motor-generator room.

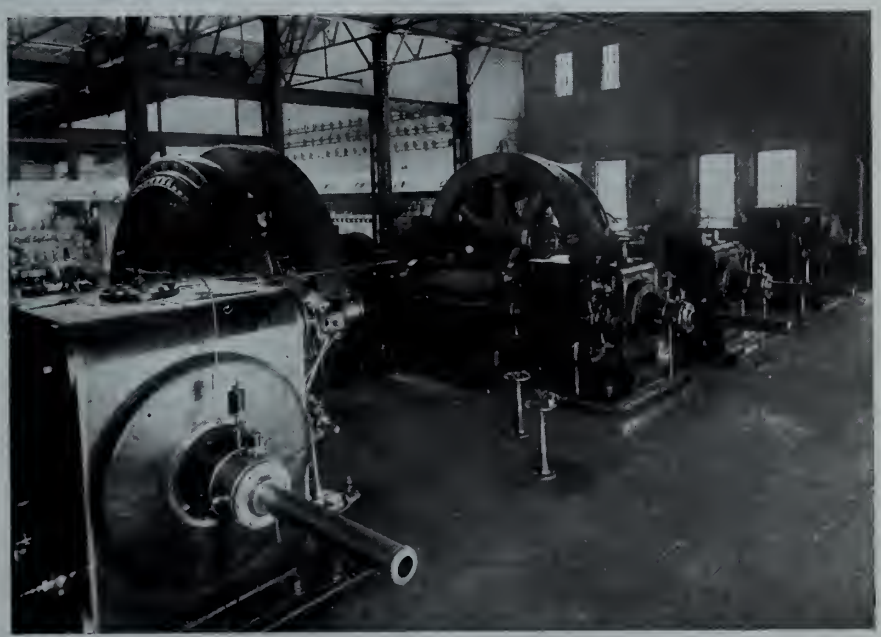
The generators are of the Westinghouse engine type and are of 1,000 k.w. capacity, delivering two-phase, 2,400 volt current, with 8,000 alternations when running at 100 revs. per min. The engines were designed and constructed by the Goldie & McCulloch Co., of Galt, Ont., and are of the cross compound non-condensing type. An initial steam pressure of 150 lbs. per sq. in., is employed, which, at 30 per cent. cut off in the high pressure cylinder, will develop 1,500 horse-power, while a maximum overload of 50 per cent. can be carried allowing an output of 2,250 horse-power per engine.

MOTOR GENERATOR DEPARTMENT. BOOSTER EQUIPMENT IN RIGHT FOREGROUND WITH SYNCHRONIZING SWITCHBOARD FOR STEAM GENERATORS BEHIND.

Special interest attaches to these units because of the high frequency of the generators and the fact that they are run in parallel with each other and also with the water-driven alternators at the main power plant at DeCew Falls, thirty-four miles distant. This is largely possible through the use of "Rites" inertia governor with which these engines are equipped, the regulation obtained by means of this device being within remarkably close limits. A variation in speed, from no load to full load, of less than one per cent. can easily be obtained, but in practice it has been found advisable to increase the variation to about one and one-half per cent. because of the fact that the response of the engines to sudden changes in load was so much more rapid than the other source of power with which they were running in parallel, that the engines were constantly overloaded while awaiting increased output from the remainder of the plant. For this reason, therefore, the sensitiveness of the engine governors was reduced so as to allow more sympathetic behaviour between the steam plant and the hydro-electric plant.

Engine Details

The high pressure cylinder is 28 in. and the low pressure 52 in. dia., giving a cylinder ratio of 3.5 to 1. Each cylinder has a stroke of 46 in., which at 100 revs. per min., gives a piston speed of 768 ft.



TWO GOLDIE & McCULLOCH CROSS-COMPOUND TRIP-VALVE ENGINES DRIVING 1000 K.W. WESTINGHOUSE GENERATORS.

per min. The valve gear is operated by a horizontal revolving shaft with four eccentrics, one to each valve. The valves are of the flat grid-iron type, seated on removable plugs which are ground into the cylinders, thus allowing the valves and seats to be scraped to a true surface before assembling in the cylinder, and also permitting of easy and rapid removal in case of wear.

As will be gathered from the illustration, the valves move across the cylinder, the trip gear on the inlet valves being controlled from the governor by a small shaft parallel with the eccentric shaft. The dash pots are carried on the outer end of the trip gear bracket and are used for cushioning only, the actual closing of the valve being done by the unbalanced steam pressure on the valve spindle. The rapidity of closing obtained by this arrangement is such that the valve gear can be run at rotative speeds up to 150 revs. per min.

REAR VIEW OF VICTORIA AVENUE SUB-STATION SHOWING TRANSMISSION LINES AND LIGHTNING ARRESTERS. BOILER HOUSE IS AT EXTREME RIGHT.

The exhaust valves are worked by a combination of links which gives a very rapid opening and closing of the valve, and a dwell during the time they are opened or closed. The use of multi-ported valves with large surfaces reduces wear to a minimum, and the placing of the valve faces horizontally insures perfect lubrication. The maximum cut-off obtainable on the inlet valves is seventy-five per cent. of the stroke.

Between the cylinders below the floor level is a reheating receiver fitted with drawn brass tubes, and a by-pass is also provided for admitting live steam to the low pressure cylinder. The tail rod bearings are adjustable in all directions so that the piston may be accurately adjusted in the cylinder.

The cross head is of the circular bearing type with babbitted shoes which are adjustable and removable, the piston rod being screwed into the cross head and secured by a heavy nut. Connecting rods of the solid end type are used, the cross head box being bronze and the crank end brass lined with babbit.

The crank shaft is made of open hearth forged steel, solid, and weighs 28,000 lbs., its diameter at the bearings is 22 in., and at flywheel and generator 24 in. Counterbalanced crank discs of semi-steel are fitted, the crank pin being ground to a taper fit, shrunk in and secured by a thin steel nut at the back.

Fly Wheel Construction

The 60 ton flywheels are of the built-up type, 18 ft. in dia., the rim being in eight sections, which are held together by wrought iron links on the two outer and also on the inner side. Each section has one arm cast integral, the inner ends of the arms being held between the hub flanges. The hub itself is in the form of two discs, the whole being held together by reamed bolts which pass through the hub and the inner end of the arms.

The engine frame is of the heavy duty type with internal ribbing. It is cast in one piece and supported for its full length on the foundation. The bearings are 22 in. dia. by 38 in. long, and are babbitted. They are of the four part type with side wedge adjustment; the outside of the shells is turned to fit the bored frame thus permitting of an easy removal of the bottom shell by rotating around the shaft. The total weight of each engine is 300,000 lbs.

The steam-generator switchboard is situated on the east side of the motor-generator department (see illustration thereof), and consists of two panels equipped with Westinghouse instruments and apparatus. The control of the engines is operated from the switchboard, a small motor being arranged on the governor gear whereby the attendant can alter the tension of a supplementary spring and thus synchronize the generators.

The office entrance and main frontage of the building is on Victoria Ave. (see illustration), and the boiler house is at the opposite corner from the office. The firing floor is about twelve feet below street level, and hand-fired Stirling boilers are installed, the use of mechanical stokers not being justified by reason of the intermittent nature of the load. To facilitate rapid pick-up under load, induced draft is employed, two steam driven Buffalo fans exhausting into a 72 in. stack, 85 ft. in height. Automatic draft control is obtained by means of a Mason regulator which operates two 4 ft. dampers, one for each bank of boilers.

As can be observed from the views reproduced, the entire plant is in excellent condition considering the number of years it has been in operation. In 1902, when the present superintendent, W. A. Sweet, took charge, there were 10 transformers of 200 k.w. each; now there are 16 transformers of 500 k.w. each. The motor-generators at that time were three in number, of 300 k.w. each, while today these are replaced by two motor-generators of 750 k.w. each, in addition to which the steam auxiliary plant was installed in 1903.

The technical activities of the Dominion Power & Transmission Co. are directed by W. G. Angus, general superintendent and electrical engineer, while the entire sub-station equipment, in Hamilton, Oakville and Brantford, is under the personal supervision of W. A. Sweet, sub-station superintendent, to whom we are indebted for much of the information and data contained herein.

HORSE POWER OF BELTING

USERS of belting are frequently misled as to the amount of work which should be got from a good belt.

The power of belting is determined by the number of foot pounds which can be transmitted by one pulley to another, and is arrived at by multiplying the effective pull in pounds per inch of width by belt width in inches and by belt speed in feet per minute; thereafter dividing by 33,000.

The effective pull or the force tending to turn the pulley is the difference in tension between the slack and driving sides of the belt and is largely dependent on the arc of contact between the belt and the smaller pulley. To find the effective pull it is necessary to determine the number of degrees in the arc of contaoct. This can be arrived at by mutiplying the difference between the pulley diameters in inches by four and three-quarters, dividing the product by the distance between the pulley centres in feet, and subtracting the quotient from 180 degrees.

The allowable working strain for a single belt with 180 degrees contact is, 40 pounds per inch width. This multiplied by the arc of contact found in the previous calculation and divided by 180 will give the effective pull allowable in pounds.

The "Howden" Sectional Type, Water-Tube Steam Boiler

By C. T. D.

With the development of an intensive shipbuilding and marine engineering activity, there has resulted both a tendency and necessity to deviate from the beaten path in the matter of design and constructional detail of a number of the prime essentials entering into one or other, or both of the twin industries. The accompanying article features a type of water-tube boiler now being made in Canada, suitable for either land or marine installation, but which has hitherto figured but little, if any, as a factor in her steam engineering practice.

THE "Howden" boiler as we find it to-day is a development of one designed in January 1861 by the late James Howden, of "forced draught" fame, and who in his lifetime was chairman of both James Howden & Co., marine machinery builders, and of the Howden Boiler Co., Govan, Scotland. As the date when the first Howden boiler was constructed occurred at a stage of marine engineering during which the use of high pressure steam for marine purposes took a sudden leap upwards, anticipating a progress which was not generally reached until fully 20 years thereafter, it will doubtless be interesting after an interval of some 56 years to chronicle the circumstances which initiated and led up to the present design.

In 1861, the usual steam pressures for marine boilers were from 20 to 25 pounds per sq. inch, beyond which it was not considered safe to operate with a salt water feed supply. Shortly before this period, however, several attempts had been made to introduce steam pressures of 100 pounds per sq. inch into steamships with compound surface condensing engines. Among these pioneers of the use of high pressure steam through compound engines and the use of fresh feed water, was the chairman of the Howden Boiler Co., who in 1859 contracted with the "Anchor Line" Steamship Co., to equip one of their Mediterranean fruit steamers with his then recently patented compound surface condensing engines and boilers to work with steam at 100 pounds per sq. inch. This steamer built by Alexr. Stephen & Sons, on the upper reaches of the Clyde, began to run in 1860, being successful and economical, running voyage after voyage without requiring overhaul or repair. Her boiler was as far as known, the first high pressure steam generator to operate successfully at sea in ordinary traffic continuously for a considerable period.

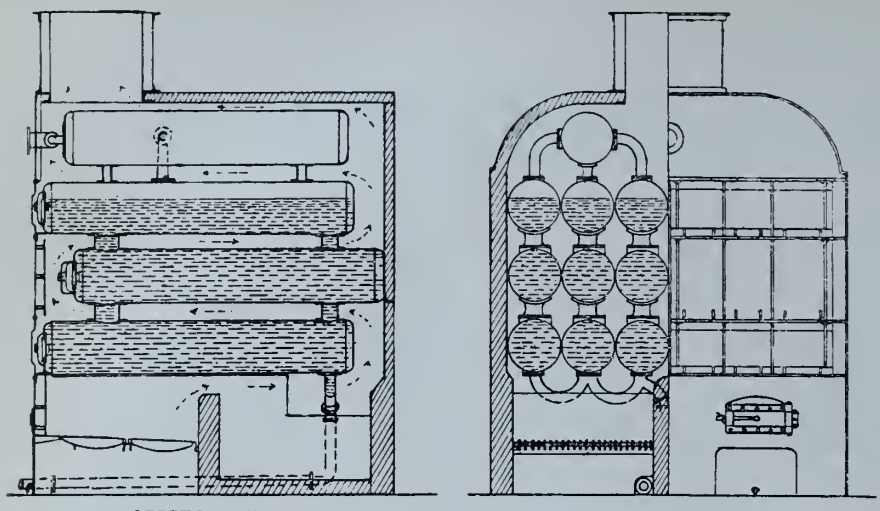
SCALE 3/4" = 1 Foot.

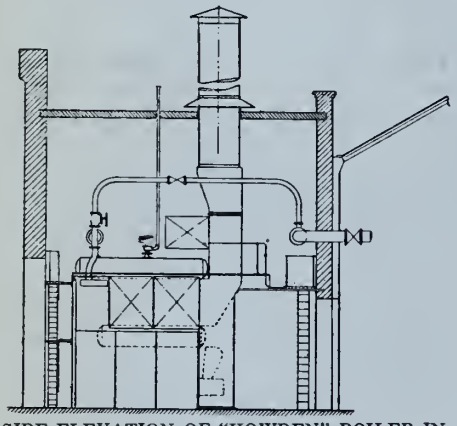
THREE ELEMENT "HOWDEN" MARINE TYPE WATER TUBE BOILER NOW BEING MADE IN CANADA.

Another screw steamer ordered about

the same time by J. H. P. Hutchison for their trade between Glasgow and Bordeaux, and built by James R. Napier, F. R. S., at Govan, had compound surface condensing engines, also boilers using 100 pounds per sq. inch steam pressure, installed. Owing to the then design of the boiler, however, and the effect of salt water from a leaky surface condenser, this vessel never accomplished a voyage to Bordeaux and back without being laid up on account of the boiler requiring overhaul and repair. Inaccessibility for cleaning and repair were drawbacks to the boilers and, with a view to giving greater convenience in these respects, a new design was developed and gave satisfactory operating results, notwithstanding the fact that leaky surface condensers were responsible for abnormal incrustation of salt on the interior boiler surfaces. The accessibility procured limited materially the heating surface, hence rapid combustion, which progress in steamship engineering necessarily entailed, was more or less negatived. The subsequent evolution of the cylindrical multitubular boiler (Scotch), with its simpler style, and greater heating surface in same space occupied, evidenced a more economical design, and being, in addition, better fitted for the marine service of that period, naturally took pride of place, and still maintains a strangle hold.

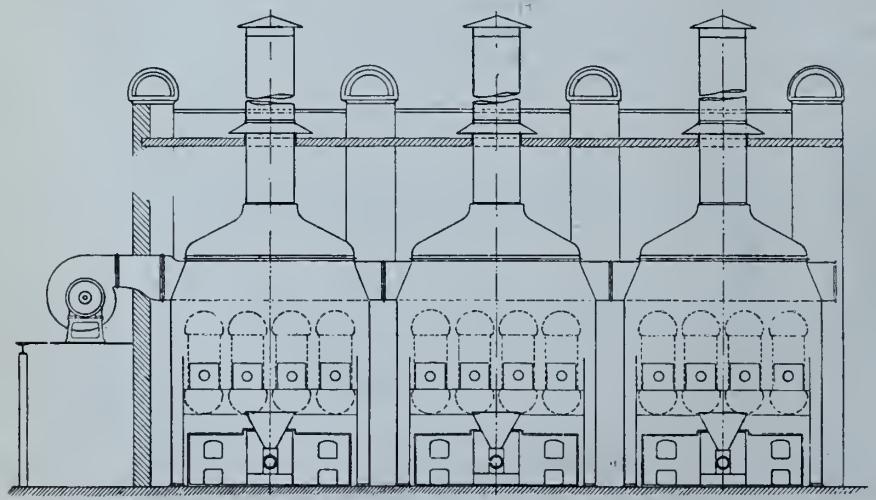


ORIGINAL DESIGN OF "HOWDEN" BOILER, JANUARY, 1861

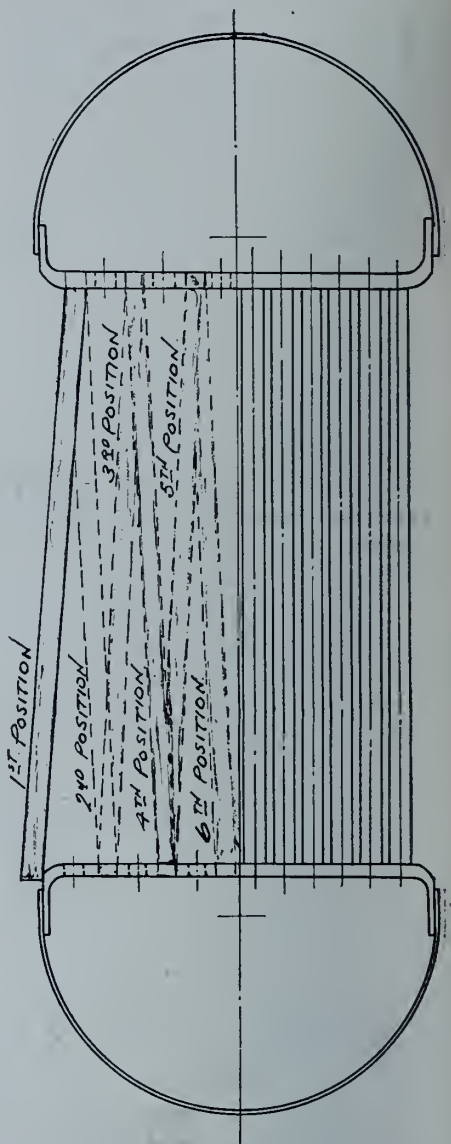


SIDE ELEVATION OF "HOWDEN" BOILER INSTALLATION AT BOROUGH OF BERMONDSEY ELECTRIC LIGHT STATION

The present Howden boiler combines an evaporation from plate surfaces, as in ordinary boilers, with the addition of that from water tubes. It is now constructed under at least three patents—1908, 1910 and 1912, respectively, the last mentioned including a design specially adapted for high speed steam vessels, where lightness and small space occupied are of vital importance, or, for use on land in places difficult of access where the several parts can be carried by men or animals and put together without skilled labor under the direction of one competent engineer. All Howden boilers are designed to be equally suitable for land or marine services. As will be noted from the illustrations, covering boilers now being built by the Polson Iron Works, Toronto, who are the licensees for Canada, the individual units are simple in character, there being the minimum of detail parts, while the sections or elements are duplicates of each other. One boiler may consist of one, two, three, four, or more elements, all the details of which lend themselves to repetition and duplicate work, therefore all parts can be made by special machinery to standard gauges, ensuring accuracy of duplication and good workmanship. The Howden boiler is adapted to work safely and economically under the highest air pres-



FRONT ELEVATION OF "HOWDEN" BOILER INSTALLATION AT BOROUGH OF BERMONDSEY ELECTRIC LIGHT STATION

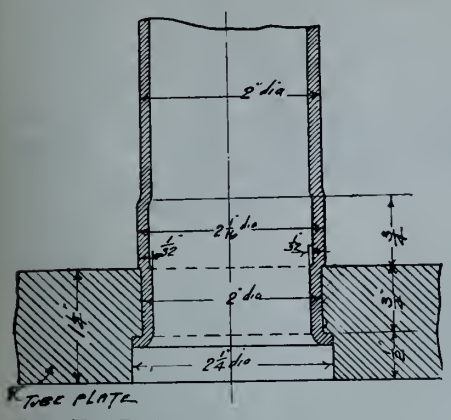


METHOD OF STEPPING-IN NEW TUBES

The worst possible position for a leaky tube is indicated. The intervening tubes are of course cut out and the new one threaded into position as shown. In consequence the holes are slightly larger in diameter than they were originally after expanding. This slackness allows the tubes to to be stepped into the various positions. The inner tubes require renewing at rare intervals.

sure of the Howden system of forced draught, and at the highest steam pressures now employed.

All parts of the boiler when working are under an equal heat, that is, no one

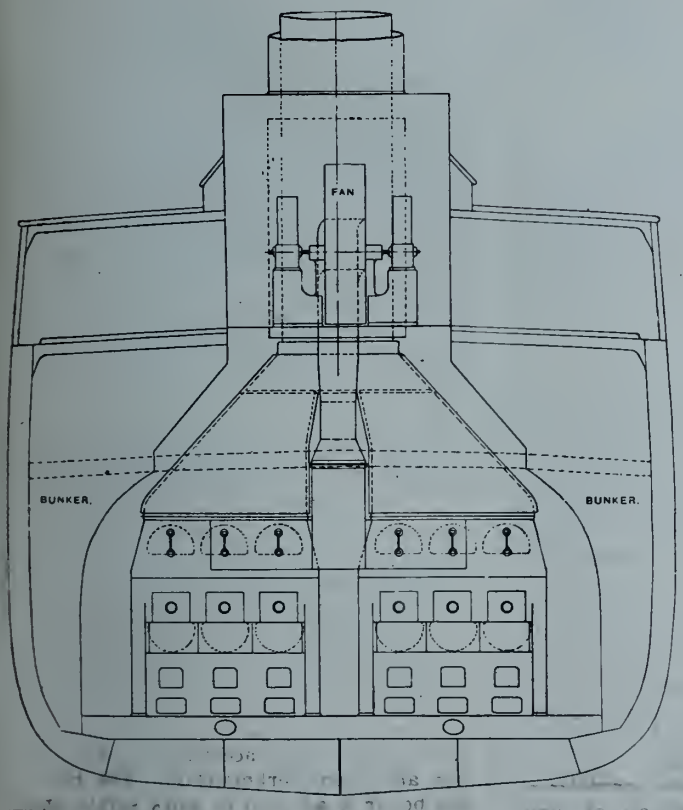


DETAIL OF TUBE FASTENING IN TUBE PLATES

Tubes cutter and extractor should be used for withdrawing tubes when possible, but if hand chisel be used, great care must be taken so as not to injure tube plates.

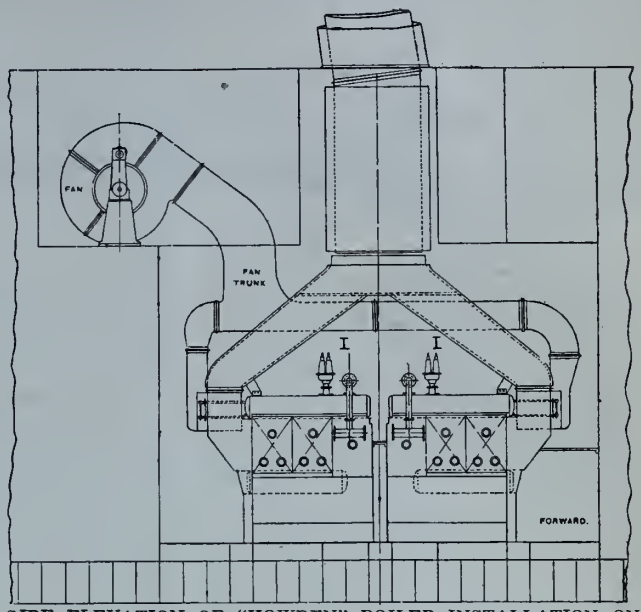
place is hotter or colder than another, while, in raising steam from cold water, all parts are brought under heat at the same time. The design lends itself to a rapid positive natural circulation without piping or other adjuncts, also to internal self-cleansing in the water tubes and drums where the water is in continual rapid movement over the surfaces exposed to the hot fire gases. In the matter of accessibility, attention is called to the fact that in a four element boiler, by the removal of eight manhole doors, the whole of the internal working parts of the boiler, that is, top and bottom drums and tubes, are at once open for examination when necessary. The fact that the tubes are short and straight is a matter of much importance, as they can all be examined in each element in a few minutes. For outside examination, the side portable doors can be quickly opened or removed, also the smokebox doors; and further, the combustion chambers are accessible by manholes from their underside, from which the back and tubes can be examined. Tubes can be removed and replaced quickly, the method of doing so being illustrated, as also the scheme of their fixing in the drum tubeplates.

In the fitting of Howden boilers into steamships, important savings are effected. Vessels which are to have cylindrical boilers installed cannot be finished completely at the yard in which they are built, as marked spaces in decks and upper works above the boiler rooms must be kept open, not only for purpose of lowering heavy cylindrical units into place by crane after launching, but the work must be finished in such a way after the boilers are on board that these decks and upper works may be opened up again to remove the boilers when they are worn out or damaged, which always takes place after a longer or shorter period of service, and in order to refit the vessel with new boilers. In large high power steamships, the cost of opening up and reclosing deck work, etc., together with that for crane service, amounts to a large sum. In the case of the Howden boiler, the several parts can be put on board by either the shipyard derricks or those of the vessel herself, being afterwards lowered to place for erection, through the stokehold hatchways or the funnel opening.



FRONT ELEVATION OF "HOWDEN" BOILER INSTALLATION ON BOARD SHIP.

The Howden boilmay be equipped with chain grates or other mechanical stokers for land installations and may be operated under either forced or natural draft, although necessarily only with the former can the highest economy and power be obtained. The boiler patents include a superheater of simple and efficient design integral with the structure of each generating unit, also



SIDE ELEVATION OF "HOWDEN" BOILER INSTALLATION ON BOARD SHIP.

a feed heater or water back forming part of the boiler evaporative surface, which is specially suitable for naval installations where reduction of weight and increase of tube surface and power in a given space are of material importance. When superheated steam is not required, the superheater can be immediately converted into ordinary heating surface, and thereby increase further the evaporative capacity of the boiler. From the illustrations accompanying, no difficulty will be experienced in grasping the detail features which go to make up either individual or combination units.

Test of No. 1 "Howden" Boiler

Heating Surface	3,125 sq. ft.
Grate Area	54 sq. ft.
Duration of Test	6 hours
Coal Burned (Bituminous Scotch)	11,058 lbs.
Coal Burned per Hour (average)	1,803 lbs.
Coal Burned per sq. ft. Grate	34.1 lbs.
Total Ash and Clinker	1,120 lbs.
Ratio of Ash and Clinker to Coal Fired	10 %
Total Water Evaporated	107,100 lbs.
Water Evaporated per Hour (average)	17,850 lbs.
Water Evaporated per lb. of Coal as fired under 192 lbs. pressure	9.68 lbs.
Water Evaporated per lb. of Coal as fired from and at 212 degs. Fah.	11.38 lbs.
Water Evaporated per lb. of Combustible at 192 lbs. pressure above atmosphere	10.7 lbs.
Water Evaporated per lb. of Combustible from and at 212 degs. Fah.	12.58 lbs.

Steam Pressure ...192 lbs. per sq. in.
Feed Temperature entering Boiler (Water Heated with Live Steam from Boiler).. 97 degs. Fah.
Temperature of Water in Feed Tanks ..... 59 degs. Fah.
Funnel Gas Temperature .....473 degs. Fah.
Temperature of Gases Entering Air Heater 545 degs. Fah.
Temperature of Air in Reservoir .....196 degs. Fah.
Atmospheric Temperature at Fan ..... 72 degr. Fah.
Air Pressure at Fan ....2⅝ inches
Air Pressure in Ashpit ....1¼ inches
Air Pressure in Furnaces .... ½ inch
Moisture in Steam (by Barrus Calorimeter.....About 1%
Flue Gas Analysis, $C.O_2$ ....14.8 %
Flue Gas Analysis, C.O. ..... Nil.
Flue Gas Analysis O. 4%
Funnel 3 ft.-8 in. in diameter, 34 ft. in height above uptake, and 50 ft. above fire grate.

Steam was disposed of during the trial by blowing off into the atmosphere. Ashes were cleaned from ashpit forty minutes preceding the start of the test, and all observable clinker removed at that time. The fires burned freely, very little smoke being observed, and that only when firing.

Three Element Boiler Detail

The illustrations on the first page of this article show the three element Howden boiler, several of which are being constructed at the Polson Iron Works Toronto, for wooden freighters being built in various yards in Canada. Although the principal features have already been summarised, a few particulars regarding the general construction will be of interest. The boiler is made up of three elements having a total heating surface of 2800 sq. ft., while the superheater has 117 sq. ft. of heating surface. The grate area for .75 in. forced draught is 45.8 sq. ft., the fire bars being 5 ft. long. The evaporation per hour from feed at 120 degs. Fah., is 13750 lbs., thus the boiler as shown in the illustration referred to above, will give a total evaporation of 1350 lbs. per hour from combined heat absorbing surface of 2800 sq. ft. and 45.8 sq. ft., .75 in. forced draught grate area, with coal of not less than 12,000 b.t.u. per lb.

The boiler is supported in steel framework in such a manner as to allow free expansion. The units are encased with brick and have doors at the side for getting at the tubes for cleaning or renewing. The feed and blow off enter the lower drum at the front head into an arrangement of internal pipes. Provision is made in combustion chamber and smoke box door for removing soot from the tubes belonging to the boiler and air heater. The forced draught is of "Howden" latest and improved type, as are also the fire doors which, when opened, automatically shut off the draught. The space occupied by the boiler including brickwork is as follows:—Width, 12 ft. 6⅜ in.; depth 12 ft. 8 ins.; and height 12 ft. 9 ins.

COMBUSTION IN FUEL BED OF HAND-FIRED FURNACES

THE rate of feeding air through the fuel affects directly the rate of combustion; that is, if the weight of air forced through the fuel bed in a given time is doubled, the rate of combustion of the fuel is doubled; if the weight of air is tripled, the rate of combustion is also tripled, and so on. In other words, the weight of air forced through the fuel bed per pound of fuel burned or gasified is constant. By increasing the rate of feeding air, only the rate of combustion is increased and not the weight of air used per pound of combustible. It is, therefore, impossible to regulate the excess of air in any hand-fired furnace by increasing or decreasing its flow through a level fuel bed.

Air Over Fuel Bed Necessary

As the gases rising from the fuel bed contain a high percentage of combustible and no free oxygen, and as the amount of air per pound of fuel can not be increased by increasing the rate of supply through the fuel bed, it is apparent that to obtain complete combustion some air must be added over the fuel bed. Thus the percentage of CO_2 in the gases in any hand-fired furnace can be controlled only by regulating the supply of air admitted over the fuel bed. This fact and the one stated in last paragraph, namely, that by increasing the rate of feeding air through the fuel bed only the rate of combustion is increased, are important in the operation of hand-fired and some other types of furnace. It is well to state in this connection that forced-draft apparatus can not supply enough air through a level fuel bed to insure complete combustion. Additional air must always be introduced over the fire in such a manner that it will mixe with the combustible gases, otherwise a large percentage of them escapes unburned.

Many a careful fireman has noticed that he makes less smoke and burns less coal if he keeps the dampers in the firing door open than when he keeps them shut tight. Frequently leaving the fire doors partly open is found helpful in reducing the smoke to a great extent and results in saving coal. In some installations special openings are provided either in the front of the furnace or through the bridge wall for the introduction of air over or beyond the fuel bed. Partly open firing doors, or special openings in the furnace, supply additional air, which burns the combustible gases rising from the fuel bed. The admission of air can be regulated to suit the rate of combustion, and at the same time maintain efficient burning of coal.

With a level fuel bed and an absolutely tight furnace, perfect combustion would be impossible even when burning anthracite coal or coke. However, such conditions are seldom or never found in practice. The firing may be done so poorly that there are thin spots or holes in the fuel bed a large part of the time. Through these holes air may enter the furnace in sufficient volume not only to make complete combustion possible, but often to raise the supply of air far beyond the most economical quantity, and cause excessive chimney losses. The fire doors never fit tight, neither are the brick furnace walls free from leaks, so that in some cases the leakage around the furnace doors and through the brickwork is far more than enough for complete combustion. Thus careless firing and a neglected boiler furnace and setting may cause the addition of air over the fuel bed to appear unnecessary.

Holes in Fire and Leaks in Furnace Undesirable

From what has been said in the last paragraph it might seem that careless firing resulting in holes in the fire, or a leaky furnace and setting, were desirable features, as they introduce additional air over the fuel bed, and thus to some extent aid complete combustion. However, holes in the fire and leaks in the furnace are most undesirable methods of introducing air into furnaces and deserve condemnation, as the amount of air introduced into the furnace can not be regulated to suit the requirements.

The holes in the fire are small immediately after the firing and grow larger as the coal burns out. Thus, when large volumes of volatile combustible are rising from the fuel bed immediately after firing and when a large amount of air is needed, the quantity of air admitted is small. As the coal burns out and the holes become larger, more air is admitted into the furnace. At the same time the volume of combustible gases rising from the fuel bed become smaller; first, because the greater part of the volatile matter has already been driven off, and, second, because holes in the fire reduce the pressure drop from the ash pit to the furnace, thereby decreasing the flow of air through the covered part of the grate, with the result that less fuel is gasified than with no holes in the fire. Therefore, less air is needed to burn this smaller volume of combustible gases, so that the quantity of air flowing into the furnace through the holes in the fire is far in excess of the amount actually needed for complete combustion. Thus when air is intraduced through holes in the fuel bed there is incomplete combustion owing to insufficient air at one time and too large an excess of air shortly afterwards.

The leakage of air into the furnace increases as the draft becomes higher, and the draft in the furnace increases as the clinker accumulates on the grate, or as the fuel bed through any cause becomes thicker. Clinker on the grate and thick fires also reduce the flow of air through the fuel bed, thereby reducing the rate of combustion or gasification of the fuel on the grate. Thus with clinker on the grate or thick fires there is a large amount of air leaking into the furnace when a small volume of combustible gases is being generated, and not enough air when the fuel bed is clean and thin and a large volume of combustible gas is being generated.

Power Transmission Section

SAFETY STANDARDS FOR POWER TRANSMISSION MACHINERY

THE specifications describe standard guards for all power-transmission equipment hereinafter mentioned, and apply to all main shafting, jack shafting, drive shafting and countershafting, and their belts and other attachments up to but not including belts actually driving machines.

Class A Guards—If the clearance between the guard and the guarded part is less than five inches, a metal guarding material that will not admit objects larger than one-half inch in diameter, strong enough to withstand loads to which it may be subjected, durable enough to withstand ordinary wear and tear, substantially fabricated and erected, and free from sharp points and edges.

Class B Guards—If the clearance between the guard and the guarded part is five inches or more, a metal guarding material that will not admit objects larger than two inches in diameter, strong enough to withstand loads to which it may be subjected, durable enough to withstand ordinary wear and tear, substantially fabricated and erected, and free from sharp points and edges.

Handrails—If the clearance between the guard and the guarded part is fifteen inches or more (measured horizontally from extreme parts within six feet of floor), a handrail forty-two inches in height with at least one intermediate rail, supported at least every eight feet, substantially fabricated and erected, with no sharp points or edges.

If constructed of pipe, the rails and posts shall be at least equal in strength to 1¼ inch standard-weight pipe.

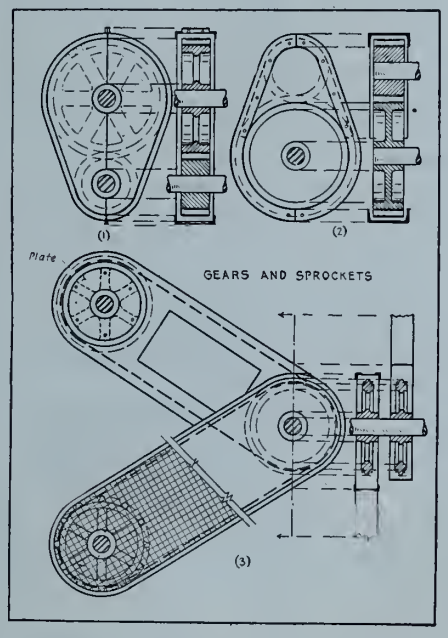
If constructed of structural metal, the rails and posts shall be at least equal in strength to 2x2x¼-inch angles.

If constructed of wood, the top rail shall be 2x4 inches, and the posts 4x4 inches, all straight-grained lumber dressed on four sides, or other construction of equal strength.

Toe Boards—When power-transmission equipment extends through floors or into pits, Class A and B guards shall extend to the floors, or toe boards six inches in height shall be provided around the floor opening in addition to standard handrails. (See Figs. 6, 7, 11, 14, 30, 31, 34, 48.)

Sanitary Bases—Class A and B guards, for power-transmission equipment not extending through floors, shall enclose exposed sides to two inches below the bottom of the lowest moving part when the clearance between that part and the floor is less than eight inches; or when the clearance between the lowest moving part and the floor is eight inches or more, the guards shall be closed on the bottom, or extended on all sides down to six inches above the floor. (See Figs. 15, 26, 36-40, 42, 43, 49.54.)

Gears and Sprockets—All power-driven gears and sprockets shall be completely enclosed on exposed sides with standard guards as specified in Class A or B, except in cases where the design and operation of the parts to be guarded



FIGS. 1 TO 3. GUARDS FOR GEARS AND SPROCKETS.

make a complete enclosure clearly impractical, in which case the face of the gears or sprockets shall be covered with a band guard surrounding all exposed teeth, with flanges on both sides extending inward beyond the roots of the teeth, and there shall be a continuous smooth web cast or fitted between the hubs and rims of the gears or sprockets. (See Figs. 1, 2, 3.)

Vertical and Inclined Belts, Ropes, Chains—All vertical and inclined belts, ropes and chains used for transmitting or distributing power (except belts traveling less than 120 feet per minute, or transmitting so little power that accidental contact therewith could cause no accident), shall be provided with standard guards as specified in Class A or B, six feet high on exposed sides, or on exposed sides and top, or with a standard handrail on exposed sides. (See Figs. 4 to 46, inclusive.)

Horizontal Belts, Ropes, Chains—All horizontal belts, ropes and chains used for transmitting or distributing power (except belts traveling less than 120 feet per minute, or transmitting so little power that accidental contact therewith could cause no accident), shall be guarded as follows:

Low Belts—If the upper part of the belt is lower than six feet above the floor or working platform, it shall be provided with standard guards specified in Class A or B, six feet high on exposed sides, or on exposed sides and top, or with a standard handrail on exposed sides. (See Figs. 47-50.)

Medium Belts—If the upper part of the belt is higher than six feet above the floor or working platform and the lower part of the belt is lower than six feet above the floor or working platform, it shall be provided with standard guards as specified in Class A or B, six feet high on exposed sides, or with a standard handrail on exposed sides. (See Figs. 51-58.)

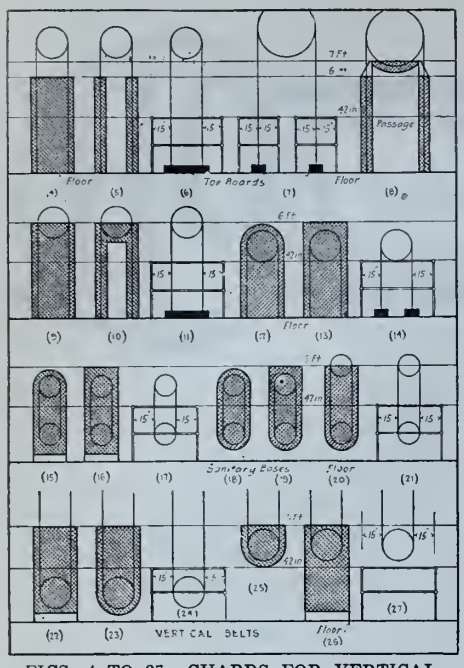
High Belts—If the lower part of the belt is higher than six feet above the floor or working platform and lower than seven feet above the floor, it shall be provided with standard guards as specified in Class A or B, on exposed sides and bottom, or with standard handrail on exposed sides. (See Figs. 59, 60.)

Belts over Driveways—Where a horizontal belt is located over a driveway or passageway, the highest floor of any wagon or truck passing beneath the belt shall be considered a working platform.

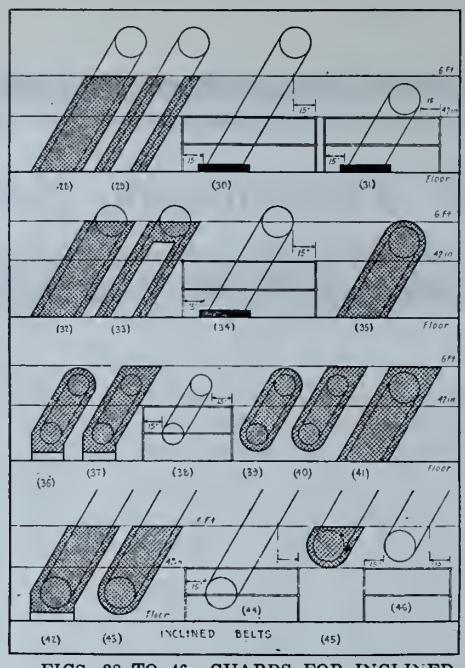
Belt Fasteners—All belts not provided with guards as specified in Class A or B and within seven feet of the floor or working platform shall be free from metal lacings and metal fasteners.

Belt Shifters—Belt shifters shall be provided for all tight- and loose-pulley belts, and shall be so designed and constructed that ordinary vibrations or accidental contact will not alter the set position, and shall have a controlling handle conveniently located. (See Figs. 61-63.)

Pulleys—Pulleys belted from above or from the side in such a way as to allow passage beneath the pulley, and within seven feet of the floor or working platform and not completely enclosed by standard belt guards or handrails, shall be guarded to the top of the pulley or to a height of seven feet above the floor or working platform on exposed sides and



FIGS. 4 TO 27. GUARDS FOR VERTICAL BELTS.



FIGS. 28 TO 46. GUARDS FOR INCLINED BELTS.

beneath by guards as specified in Class A or B, or be enclosed on exposed sides by standard handrails. (See Figs. 64-67.)

Bearing Clearance.—The clearance on shafting between pulleys and bearings or between pulleys and fixed objects shall be not less than thirty-six inches and wider than the belt, or the pulleys shall be guarded on the near side with stationary guards as specified in Class A or B, and all revolving objects in the clearance shall be smooth, cylindrical and concentric with shafting. (See Figs. 68-73.)

Belt Clearance—The clearance on shafting between pulleys and pulleys, collars, couplings or other revolving attachments shall be wider than the widest belt used, or the pulleys shall have flanges or guards to prevent the belt from dropping into the clearance. (See Figs. 68-73.)

Abandoned Pulleys—Pulleys without belts shall be guarded as though belted, or removed from revolving shafts.

Clutches—Friction clutches, jaw clutches and compression clutches within seven feet of the floor or working platform or within thirty-six inches of a bearing shall have their operating mechanism completely enclosed in stationary guards as specified in Class A or B, or in smooth, concentric revolving guards of solid construction with no projecting parts or attachments.

Couplings—All couplings within seven feet of the floor or working platform or within thirty-six inches of a bearing shall be guarded as follows:

Rigid Couplings—Sleeve couplings and flange couplings shall be cylindrical and concentric with the shafting and with no parts or attachments projecting beyond the largest periphery of the coupling or its projecting flanges. (See Figs. 74, 75.)

Flexible Couplings—Flexible and universal couplings shall be completely enclosed in standard stationary guards as specified in Class A or B, or in smooth concentric revolving guards of solid construction.

Clamp Couplings—Clamp couplings and makeshift devices of irregular shape or unknown strength are prohibited on power-driven shafting.

Collars—Assembled collars shall be smooth, cylindrical and concentric with shafting, with no projecting parts or attachments. See Figs. 76, 77.)

Set Screws—All set screws in revolving parts not enclosed by standard guards as specified in Class A or B shall be flush with or countersunk below the periphery Figs. 76, 77.)

Keys—All keys or keyways in revolving shafting not enclosed by standard guards as specified in Class A or B shall be made flush with the end and periphery of the shaft or enclosed by smooth, cylindrical concentric guards.

Vertical Shafting—Vertical shafting with or without collars, couplings, clutches, pulleys, or other attachments shall be enclosed on exposed sides with standard guards as specified in Class A or B to a height of six feet above the floor or working platform, or with a standard handrail. (See Figs. 78, 79.)

Horizontal Shafting—Horizontal shafting with or without collars, couplings, clutches, pulleys, or other attachments, including dead ends, within seven feet of the floor or working platform, shall be enclosed on all exposed sides with standard guards as specified in Class A or B or with standard handrail, or with freely revolving tubing. (See Figs. 80-82.)

Shafting over Driveways—Where horizontal shafting is located over driveways or passageways, the highest floor of a wagon or truck passing beneath the shafting shall be considered a working platform.

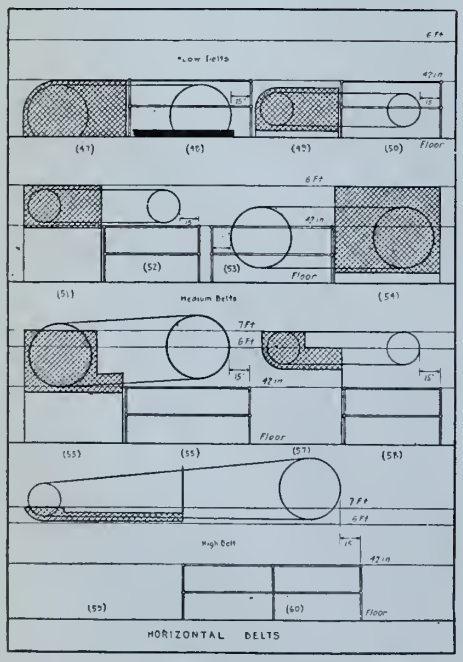
Emergency Stop Stations—A station or stations shall be provided in each room, section, or department to stop immediately all power-transmission equipment therein. Such station or stations shall be properly marked and easily accessible and provided with means for locking in "stop" position.

Bearings—Where possible, bearings shall be of a self-oiling type with reservoir capacities for at least 24 hours' running or shall have other methods of oiling which do not bring the oiler in the danger zone, and shall have necessary drip cups and pans securely fastened in position.

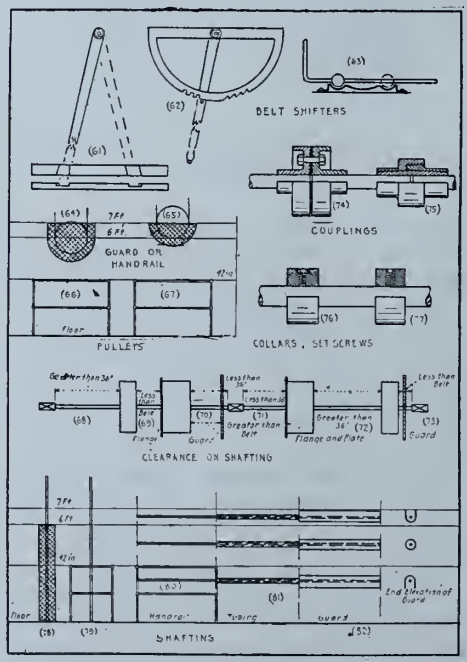
Lubrication—Oiling which brings the oiler in a danger zone shall be done only by an authorized person, and while the machinery is not in motion.

Oiler's Clothes—The oiler must not wear loose or flowing clothing.

Oiler's Lock—The oiler shall be provided with a lock and key or with a key to the locks at the emergency stop stations, and with a warning sign to display at the stations when at work on ma-



FIGS. 47 TO 60. GUARDS FOR HORIZONTAL BELTS.



FIGS. 61 TO 82. GUARDS FOR MISCELLANEOUS EQUIPMENT.

chinery controlled by that station. He shall be required to lock the station in a "stop" position and display the sign before going to work, and unlock and remove the sign when the work is completed and all men have left dangerous places.

Starting Signals—Ample notice should be given by means of an effective alarm or signal in all departments before power-transmission equipment is started.

Inspection — All power-transmission equipment should be carefully inspected at frequent and regular intervals by foremen or authorized inspectors, and defective equipment should be reported for repair and records kept of inspections.

Repairs and Adjustments—Repairs and adjustments to power-transmission equipment or guards therefor shall be made only when the power is cut off from that equipment, and guards shall be replaced in protective before the power is cut on.

Removing Guards—Guards installed in accordance with this Code shall not be removed or rendered ineffective.

The foregoing constitutes the tentative draft of a Code of Safety Standards for Power-Transmission Machinery compiled by Carl M. Hansen and Rufus W. Hicks under the direction and with the consent of the Committee on Health and Safety, National Association of Manufacturers, and presented at this year's spring meeting of the American Society of Mechanical Engineers. An author's note states that the use of properly designed, constructed, and installed individual motor-driven equipment with electrical power distribution not only eliminates many of the hazards demanding this Code, but also gives an uninterrupted distribution of natural and artificial light, and a greater flexibility and range of speeds than is possible with mechanical power distributing systems.

HANDY CHART FOR BOILER SHELL COMPUTATIONS

By W. B.

THE accompanying chart will be found useful for determining three different things:

1.—It will give the shell thickness of the boiler, knowing the pressure in pounds per sq. in., and knowing the diameter of the boiler in inches.

2—It will give the pressure in pounds per square inch when the other two factors mentioned in (1) are known.

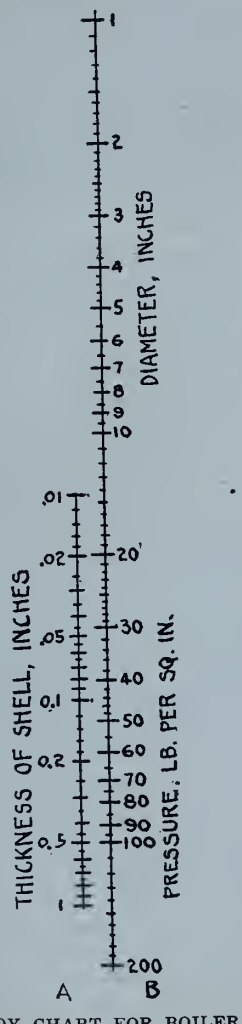
3—It will give the diameter of the boiler in inches when the other two factors also mentioned in (1) are known.

For example, given a boiler made of mild steel, whose internal diameter is 34 inches, and whose shell thickness is .25 inch. What pressure may be safely held within the shell? ?

Find the 34 in column B and measure the distance down to .25 in column A. Then from the .25 measure downward that self-same distance, and the answer will be immediately found in column B as 150 pounds per square inch. This chart is based on 10,000 pounds per square inch as the safe stress to which the metal can be subjected, therefore the answer is the safe working pressure to which the shell can be subjected.

In case it is desired to find the thickness of shell, knowing the other two factors, all that is necessary is to locate the two known points in column B and then find the mid-point. The answer is to be found directly opposite that mid-point in column A.

To find the diameter to which a boiler can be safely made, knowing the shell thickness, and knowing the pressure, the operation is practically the same as in the first example cited. This will be better understood when it is pointed out that the shell thickness would have to be



HANDY CHART FOR BOILER SHELL COMPUTATIONS.

the same for a pressure of 34 pounds and a diameter of 150 or for a pressure of 150 pounds and diameter of 34 inches. Do you get the point? That is why the chart is reversible.

The range of the chart is wide enough to cover nearly every common boiler condition. Its highest pressure is 200 pounds per square inch and the highest shell thickness is one inch.

In case the metal is steel, this chart is especially applicable, allowing a factor of safety of nearly six. In other words, where the breaking strength of the metal is 60,000 pounds per square inch, this chart automatically includes the factor of safety of six. If the metal is cast iron, or something weaker, the chart will not hold without allowance being made.

BEARING LUBRICATION

A STUDY of the influence of surface velocity on the mean film thickness in the lubrication of bearing forms the subject of the paper which received the student prize of the American Society of Mechanical Engineers in 1917. The paper was prepared by Boynton M. Green, of Leland Stanford, Jr., University.

The apparatus used in the experiments on which the paper was based is shown in Fig. 1. It is non-adjustable and consists of a plain phosphor-bronze sleeve about 3¼ in. in diameter and 7 in. long, pressed into a cast-iron housing which was bolted to a lathe bed. Lubrication was effected by two steel oil rings of rectangular section. Two sets of oil grooves were cut in the upper half of the bronze as shown in the sketch. On assembling the bronze sleeve and housing it was found that the bronze was elliptical in section, the major axle being vertical. The average difference in diameters was 0.001 in.

While for best results the sleeve should have been reamed after pressing it into the housing, the inaccuracy did not seem to affect the results appreciably. The journal was a piece of mild steel ground to a diameter of 3.244 in., giving a running fit allowance of 0.0035 in., or about 0.001 in. per inch of diameter. On each end of the journal a 67-lb. cast-iron flywheel was secured by a nut. The total weight of the assembled journal, flywheels and nuts was 165.5 lb., making a nominal load on the bearing of 7.275 lb. per sq. in. of projected area. The entire apparatus was mounted on two parallel lathe beds, and three lathe heads with four-step pulleys were utilized for the drive. To locate the position of the journal relative to the bearing, three micrometers were used, spaced 120 deg. apart around the bearing in a plane through its centre and perpendicular to its axis.

In determining the mean thickness of oil films, the following approximations were made:—(a)—The loaded portion of the film was that below the horizontal plane through the centre of the bearing. (b)—The thickness of the film at this plane and on each side of the journal was equal to the radial bearing allowance. (c)—The mean thickness of film was the average of the thickness at this plane and the minimum thickness of the film. The minimum thickness of the film is the radial allowance minus the distance between axes of the journal and bearing.

The curve plotted from the results gave the general equation:

$$y = b + c^a \sqrt{V}$$

in which y = means thickness of film in inches.

b = one half the radial allowance.

c = constant, dependent on allowance and possibly on viscosity.

a = constant, dependent on viscosity and possibly on allowance.

V = surface velocity of journal in feet per minute.

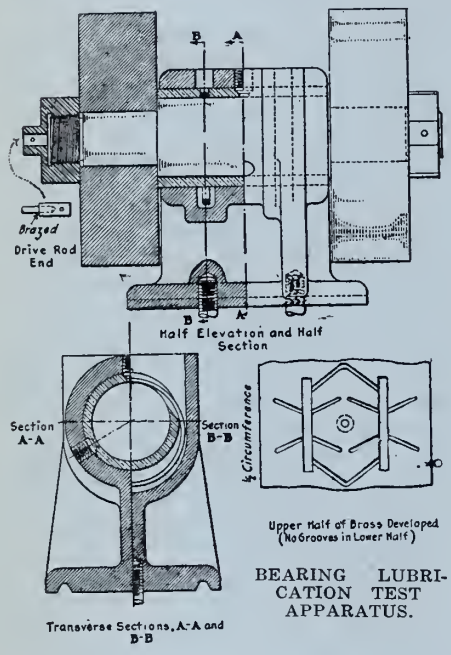
From the experimental figures the values of c and a were found to be: c =

0.0000049; a = 1.8, and the resulting empirical equation is

$$y = 0.0000049^{1.8} \sqrt{V}$$

As to the application of the empirical equation in the general equation for bearing lubrication, it may be said that it can be used directly for conditions of the same allowance and the lubricants having the same viscosity. For other allowances and lubricants the change of (c) and (a) cannot be stated definitely. In general (c) will change with some function of the allowance and (a) with some function of the viscosity.

The oil used during the experiment was an ordinary mineral oil known as "vacoline," manufactured by the Standard Oil Company. Its viscosity was given by the Engler viscosimeter as 11.0 at 20 deg. C. and 2.95 at 50 deg. C., compared with water at 20 deg. C., which gave a specific viscosity of 38.9 at 20 deg. C. and 8.7 at 50 deg. C.—"



BEARING LUBRICATION TEST APPARATUS.

POWER TRANSMISSION BY CHAIN

ALTHOUGH the question of power transmission is only one of many to which the engineer has to give his attention, yet in these days of great and increasing activity, it comes about that none of us can afford to be indifferent to any factor which makes for better, quicker or cheaper production. Plants, factories and mills are extending in every direction as the supply falls short of the demand, and it is the engineer with the knowledge of where to save, who is mainly responsible for these extensions. That chain driving, which has many advantages over other methods of power transmission in many cases is a factor of considerable importance, is evidenced by the fact that in every part of the world engineers are using this drive to a large extent. Space does not permit us to discuss the design of chains and their many applications, opportunity will therefore only be taken to summarize a few of the advantages accruing from their service adoption.

The chain drive is positive, inasmuch as the chain cannot slip on the wheels. It is elastic, inasmuch as the weight of the chain which hangs between the wheels may act as a spring; the lubricant in the bearings, and in certain cases even the shape of the links adding to this quality. The effect of this elasticity is to considerably reduce the vibration and noise inseparable from such a positive power transmission as spur gearing, while the positive nature of the chain drive has in many cases increased the production of machines from 15 to 30 per cent.

Chain driving is highly efficient; experiments having shown that the efficiency of a well-designed chain drive is somewhere between 97-98½ per cent. Also, the nature of the action of the chain upon the wheels is such that this high efficiency is maintained throughout the life of the drive, and is not seriously affected by minute inaccuracies of erection, as in the case with some forms of tooth gearing.

As compared with rope or belt, the centre distance for chain driving never exceeds 8 feet or 9 feet and can, if circumstances require, be made so small that the chain wheels barely clear one another. For this reason it is even possible to take out a pair of spur wheels, replace them by chain wheels of smaller diameter and get, as the result, a highly satisfactory drive as regards efficiency and absence of noise and vibration.

Partly on account of the above advantages, and partly because it is not necessary that there should be any greater initial tension in the chain than such as is caused by its own weight, there are very heavy incidental economies, effected by chain driving. The absence of tension results both in saving of power and in reduction of wear and tear of bearings, shafting and machine parts.

Chain Drive Limitations

There are many locations and conditions particularly suited for belts, ropes and gears, and these systems will never be discarded; yet as the system of power transmission by chain has become more widely known, its advantages have been quickly appreciated and its popularity greatly increased among prominent Canadian firms. Chain driving, of course, has its limitations; for instance, where power has to be transmitted at right angles, or where the driving and driven shafts run in opposite directions. This latter instance in itself debars its use on fully half the machine tools in service, and where otherwise it would be applicable. Chains are not affected by moisture, heat or oil; belts and ropes tend to slip under such conditions, with resultant loss of power accompanied by destructive heat. It was, however, in cases where shafts were too far apart for gears, and too close for belts or ropes, that chains made their debut. Their success in these fields suggested trials in others.

Quiet Running and Compactness

In many instances, the gear makes no greater sound than a medium-sized belt. It is impossible to have metallic pieces moving with absolute silence, and its degree is affected by the speed of the chain and the number of teeth in the sprockets. Noise is only produced when the chain speed is excessive, and when the number of teeth becomes very low.

Compactness is probably one of the most important advantages chain transmission offers over belts or ropes, and it secures admission for the system into an unlimited field of application. The chain sprockets are approximately one-half the size of belt pulleys of the same capacity, and they may be placed quite close together, thus economizing in space, and often providing a more convenient and satisfactory arrangement of machines. Again, the width of the chain is usually about one-third the width of a belt for the same power.

First Cost

To many, the first cost of a chain drive is an obstruction; this being about 50 per cent. for small powers, and as low as 35 per cent. for large powers, higher than a belt drive of equal capacity. It should be borne in mind, however, that higher efficiency, saving in power and increased production, mean more satisfactory transmission at low cost. There are several hundred chain drives in use in Canada, a large majority of which are transmitting upwards of 200 h.p., with centres as short as six feet.

ROPE TRANSMISSION

THE main features of an ideal rope-drive are that the diameter of the pulleys shall not be less than thirty times the diameter of the rope used, and the driving and driven pulleys shall, if possible, be of equal diameter, but where this cannot be arranged, their ratios should not be greater than 5 to 1. The distance between the pulley faces should, if possible, be not less than 25 feet, and the drive should be horizontal, with the slack side of the rope on the top. The speed may be from 2,000 feet to 4,000 feet per minute, but if too low the ropes are apt to slip, and if too high, the action of centrifugal forces affects the efficiency.

There should be a distance of from 4 to 6 feet clearance under the ropes, and these must, of course, not rub on anything. An allowance of 2 or 3 inches clearance between the bearing foundations and the sides of the pulleys must be made so as to leave room for the ropes to be put on to the pulley. The pulleys must also be accurately in line, well balanced, and the grooves exactly alike.

All gears between the prime mover and the rope-drive should, if possible, be avoided; the ropes should be kept dry, properly lubricated, and not too tight. They should all be put on at one time, and the full load applied to them as soon as possible after they are in place. Carrier pulleys, rollers, and angular drives should be avoided as much as possible.

Rope driving is applicable and works satisfactorily in cases of indirect as well as direct requirement.

Practice of Oil Burning Under Stationary Steam Boilers*

By B. S. Nelson

The scarcity and high price of coal for steam raising, etc., has naturally directed attention to the subject of oil fuel as a substitute. In recent years much progress has taken place in the direction of high degree efficiency of equipment for oil burning, and many installations have been made in consequence. While there is little prospect of an oil scarcity devloping, there is nevertheless a tendency for its price to soar, a very material increase being noted in the period covered by the war to date. Advantages of oil over coal, aside from cost, are dealt with in the accompanying article, and are worthy of close study.

FUEL oil is oil which is more valuable to the producer as fuel than as a refined product. Due to the rapid increase in use of gasoline in motor vehicles and the use of distillates in stationary engines, and also to the improvements in refining crude oils, it is probable that very little crude oil will be used for fuel, and that the fuel most used will be some sort of residuum or scalped oils; that is, being distilled and the residue used as fuel. The result of this will be that more attention will have to be paid to the oil-burning system than was necessary with the lighter crude oils used heretofore, because a scalped oil is heavier and more viscous than crude oil. One advantage in using a scalped oil is that there is less fire risk, because its flash point is higher than the flash point of the crude oil.

The flash point of an oil is of interest particularly from the standpoint of safety. On land installations, where the oil is usually buried in a closed tank, the flash point is of less importance than on shipboard, where inflammable vapors are apt to accumulate in the hull or to be freed in a closed boiler room, due to leaky piping.

The viscosity of an oil is the principal

FIG. 1. TEMPERATURE VISCOSITY DIAGRAM OF FUEL OILS, REPR ODUCED FROM CURVES OF LT.-COM. JOHN J. HYLAND, U.S.N., WITH ADDITIONS (SHOWN IN DOTTED LINES) BY E. H. PEABODY.

the oil from which the lighter constituents have been distilled off. Though the Mexican oils are, as a rule, heavier and contain less of the lighter constituents than American oils, even they are now

*From a paper presented at a joint meeting of the Louisiana Association of Members of the American Society of Civil Engineers and the New Orleans Section of the American Society of Mechanical Engineers.

Fuel Oil Classification

Fuel oils may be classified according to several of their characteristics, which are more or less dependent upon each other. Some of these are the flash point, or temperature at which an oil will give off inflammable vapors; the viscosity, which may be explained as the molecular friction; the specific gravity, the heat value, and the sulphur content.

consideration in the actual burning of that oil, because the success of the burner or atomizer depends largely on its ability to atomize the fuel into sufficiently fine particles to insure satisfactory combustion, and the more viscous the oil the more difficult this atomization. There are various methods of expressing the viscosity, one of the most used being in terms of the Engler scale. Degrees

Engler means simply the ratio of the time it takes a given quantity of an oil to flow through a standard orifice as compared to the time it would take the same volume of water to flow through. Oil is usually sold, however, on the basis of its specific gravity (generally measured in degrees Baume) and its heat value and moisture content. It is usually assumed that the heavier an oil in degrees Baume, the more viscous is that oil, but this is not always strictly true.

Through the courtesy of E. H. Peabody, Mem. Am. Soc. M.E., in Fig. 1 is reproduced a very interesting chart giving the characteristics of some thirty different oils. This chart gives the temperature-viscosity diagram of these fuels, the specific gravity, the degrees Baume and the flash point. Comparing two crude oils from these curves brings out the relation, or rather lack of relation, between degrees Baume and degrees Engler:

	Deg. B.	Flash Pt.	Deg. Eng. at 230 Deg. Fahr.
Panuca Crude	13.7	140	13.75
No. 18 California.	12.7	285	5.2

It is to be regretted that oil is not specified in terms of specific gravity instead of degrees Baume, because in any calculations involving the weight of the oil per gallon or per barrel it is necessary to refer back to specific gravity. Further, the heaviest oil that can be designated on the Baume scale for liquids lighter than water is 10 deg. B., or unit specific gravity. There are oils being used now of 10 and 12 deg. B., and no doubt still heavier oils will be used, which will call for two different Baume scales and cause confusion.

Spindle Top oil has a specific gravity of about 0.92, corresponding to 22 deg. B., and its heat value averages about 19,700 B.t.u. California oil is somewhat heavier, the average grade of that oil having a specific gravity of about 0.95, or 18 deg. B., heat value about 18,500 B.t.u. The Mexican oils vary considerably in specific gravity and heat value, but as a rule they are much heavier than either the California or Texas oils; a typical oil now used has 0.99 sp. gr., or 12 deg. B., with a heat value of about 18,200 B.t.u.

Table I compares the prices of coal and oil, taking as a basis coal of the quality of Pratt, Alabama, and Pittsburgh coal, sold in the New Orleans market. While with these coals an evaporation of 10 lb. from and at 212 deg. can be realized with well-designed water-tube boilers when the boilers have ample heating surface and are in the hands of skillful firemen, it is extremely doubtful if any boilers in regular service are showing better than 8 lb., and the great majority are below this figure. Therefore, if we take 8 lb. as a basis, we are giving the coal its full value. Now, with oil giving 19,500 B.t.u. per lb., an evaporation of 14.5 lb. should be readily obtained if the apparatus for supplying the oil to the furnaces is of first-class design and if the furnaces are properly arranged. With this ratio as a basis, it is apparent that a pound of coal is equivalent to 8/14.5 or 0.541 lb. of oil. A barrel of crude oil weighs approximately 325 lb., therefore one ton (2000 lb.) of coal is equivalent in practical heating value to 3.34 bbl. of oil.

TABLE I—COMPARISON OF PRICES OF COAL AND OIL.

Coal, Dollars per Ton, 2,000 lb.	Oil, Dollars per Bbl.	
5.00	1.50*	1.66†

2.25	.68	.75

*Not allowing for labor saving.

†Assuming 10 per cent. of cost of fuel in labor of firing and handling ashes saved by using oil, a conservative estimate for plants of over 300 h.p.

An interesting point to note with reference to the heat value of an oil is that the B.t.u. usually given is the high heat value or heat value determined in a bomb calorimeter. The actual heat value available in a boiler furnace is less because all fuel oil contains a considerable percentage of hydrogen, and the latent heat of the steam formed by the combustion of this hydrogen passes up the stack as waste heat.

In all the heavier grades of fuel, particularly the Mexican oils, water mixed with the oil is in the form of an emulsion and will not settle out in a tank as it will with the lighter American crudes. This is not so much a disadvantage as it would seem, other than causing a lowering of the heat value. With an oil light enough for the water to settle out of its own accord, this water will frequently accumulate in the tank and piping and go over into the burners in a slug, putting the burners out; but with heavy oil a very considerable amount of water can go through the burner with no bad effect. The writer is inclined to believe that a small quantity of water in heavy oil is an advantage in that these oils are usually heated above the boiling point of water to effect atomization, and the vaporizing of the moisture in the oil as it leaves the burner tip probably helps to atomize the oil more thoroughly.

Oil Advantages Over Coal

Oil has numerous other advantages over coal than cost of fuel. The storage space required is much less for an equal number of heat units; there are no ashes to be disposed of; less boiler-room help is required for firing; the wear and tear on the furnace lining is smaller because the firedoors do not have to be opened, with the consequent chilling of the hot brickwork. Very few repairs are necessary to the grate bars; a much smaller stack can be used for the same boiler horse-power; the boiler can be forced with natural draft considerably beyond what it can with coal, an important feature where boiler capacity is scant; where feedwater is bad, it is often possible to carry a load with two oil-fired boilers which would require three boilers were coal used, thus allowing the cleaning and repairing of one dirty boiler at a time. Steam can be raised much more quickly and with no loss due to banking fires. It takes about 10 per cent. of the fuel normally consumed by a boiler at rated load to keep its fire banked with coal. In case of an emergency the fire can be instantly extinguished; any one who has had to draw a hot coal fire in an emergency can appreciate this particular advantage.

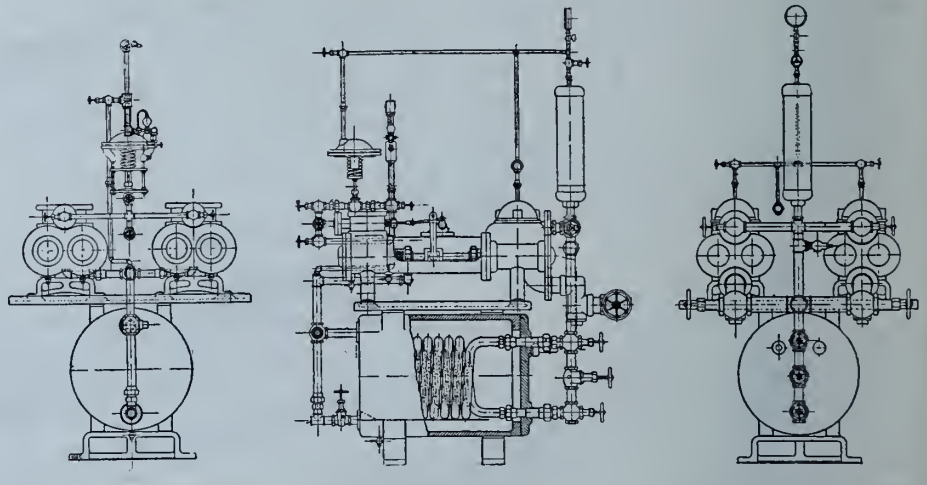

FIG. 2. OIL PUMPING SET, SHOWING DUPLICATE PUMPS WITH PRESSURE GOVERNOR, AIR CHAMBER, GAUGE, SUCTION STRAINERS, RELIEF VALVE AND HEATER.

Successful Oil-Burning Installation Data

There are several factors entering into the successful oil-burning installation, some of which affect the reliability of the system and others its efficient operation.

The first consideration for reliability is the oil supply to the burners, involving the storage tanks, pumping outfit, and heaters. The size of a storage tank varies, of course, with the size of the boiler plant, but it should be large enough, at least, to hold a carload of oil. A very popular size of tank is a 10,000-gal. tank, which is about 8 ft. in diameter and about 30 ft. long. These tanks are usually built of ¼-in. steel with ⅜-in. heads, though if the tank is subject to corrosion from the outside it should be made of heavier material. The tank should be equipped with a manhole and filling pipe, a suction opening, a vent opening, and openings for steam-heating-coil connec-

tions. The insurance requirements call for the tank to be below the level of the pumps and burners, which means that it is usually buried in the ground.

The Oil Pumps

The oil pumps are the next consideration. The pump that has given the best results is a duplex steam pump, piston-pattern type, with brass valves, metallic packing in the oil piston and special gaskets and piston-rod packing. The size of pump should be based on a very low piston speed.

The pump should be fitted with an air chamber on the discharge side to steady its pulsation of pressure, and a governor on the steam end to maintain the pressure constant. The pressure at which the oil is delivered to the burners depends largely on the character of the oil, varying from 40 lb. for oil of 26 to 30 deg. B. to 80 lb. for oil of 12 deg. B. The pump should also be equipped with strainers on the suction side to keep trash from getting under the pump valves. Duplicate pumps should always be installed, so that if anything goes wrong with one pump the other may be put in service.

The pump should be set as near the level of the oil as possible to give the minimum suction lift, and the suction pipe should be as straight as possible, preferably with bends instead of elbows. Where the suction pipe is long, a foot valve at the bottom of the suction line in the tank is desirable. This should be a valve without leather seats, as fuel oil deteriorates leather. A very good valve to use is a horizontal-swing check used in a vertical position. In addition to air chamber and governor, the pump should be equipped with a relief valve set at a pressure heavier than the working pressure, so as to minimize the danger of breaking the pump. This relief valve should be of the enclosed type, so that its overflow be returned to the tank.

The heavier oils require heating in the suction tank in order to enable the pump to lift them. The temperature must not be high enough to cause the oil to vaporize under the suction pull of the pump. The writer has found a temperature of 110 to 130 deg. about right for Mexican oil of 12 to 18 deg. B. According to Commander John J. Hyland, U.S.N. (*Jour. A. S. N. E.*, May, 1914), the viscosity of the oil had to be reduced to 375 deg. Eng. in order to obtain full capacity from a Blake pump. In order to gauge this temperature accurately, a thermometer should be installed in the suction line near the pump. If this suction line is long, or has several elbows in it, it should be made one or two sizes larger than the suction opening of the pump.

The Heater

The next question is that of the heater. Practically all the oil now burned as fuel requires heating in order to reduce its viscosity and facilitate atomization at the burner. There is a wide choice of heaters, but the principal considerations are, first, to have the heater of ample heating surface, and second, to be sure that this heating surface is all utilized. In heating oil with a steam coil in a vessel of oil there is a tendency to local heating; that is, the oil next to the coils may be very warm; but this heat is not readily transmitted to the adjacent oil, so that a heater in which the oil is kept in rapid motion over all the heating surface in the coil is apt to give best results.

There are several pumping sets on the market which combine all the requisites enumerated above in one self-contained unit. Fig. 2 shows such an outfit which, it will be noted, consists of duplicate pumps with pressure governor, air chamber, gauge, suction strainers on pumps, relief valve and heater.

Oil Heating Temperature

The temperature to which the oil must be heated naturally varies with its viscosity. For fuel oil usually burned in the South, a temperature from 180 to 220 deg. is satisfactory, the higher temperature being for oil of 12 deg. B. As far as we know, no experiments have been made to determine the degrees Engler to which oil must be heated, but judging from our experience and with the aid of the temperature-viscosity diagrams, we should say that about 8 to 9 deg. Eng. is the viscosity required for a steam-atomizer burner. It has been stated, however, that any oil which can be pumped readily can be atomized by a steam atomizer. After the oil is heated at the pump (and its temperature should be read by a thermometer permanently fixed in the discharge line from the pumps), care should be taken to keep the oil hot until it reaches the burner by proper covering of the pipes.

Burner Feature

More stress has probably been laid on the oil burner than on any other part of the installation, which has led to the belief on the part of people unfamiliar with the burning of oil that the burner is the whole thing, whereas, as a matter of fact, the burner contributes but a very small part to the success of the installation. The term burner is really a misnomer, because the only function the burner performs is to atomize the fuel into sufficiently fine particles to effect complete combustion in the furnace.

For land installations, the type of burner which has proved best is the steam-atomizer burner with oil supplied to it under pressure. The essentials of such a burner are simplicity, cheaply renewable wearing parts, economy in steam for atomizing, and the production of a flame of such shape that makes good combustion and, hence, high boiler efficiency possible. The burners may be of either the round-flame or flat-flame type. The flat-flame type is preferable because it uses less steam for atomizing and produces a flame of such shape as to permit proper mixture of air to support combustion without excess air, which is not the case with a round-flame burner.

The use of a target wall is not necessary, and may cause injury to the heating surface of the boiler by causing the flame to concentrate on a small portion of the surface, resulting in what is termed "blow-pipe" action.

The general type of flat-flame burner is a tip in which are two narrow parallel and horizontal slots, the oil flowing out of the upper slot in fan shape on to the fan-shaped jet of steam issuing from the lower slot.

The position of the burner depends largely on the type of boiler. For a boiler with a long unobstructed furnace, such as a horizontal return tubular, or a boiler of the Heine or Erie City type, a burner set in the firing door is very satisfactory. For boilers where the furnace is short and the travel of the gases is upward, such as in the Babcock & Wilcox or Stirling boiler, the best arrangement is to put the burner at the back, shooting toward the front of the boiler. In either case air should be admitted to the furnace through a checkerwork of firebrick laid on the grate bars. The shape of this checker work should approximate the shape of the flame and thus reduce excess air, and the area of all the holes should be equal to 4 sq. in. per boiler horse-power.

Steam and oil connections to a burner should be made to allow for the expansion and contraction of the oil and the steam headers, and should have unions above and below the burner to enable the latter to be taken out quickly for cleaning. A very essential point in installing a burner is to see that it gets dry steam. The simplest way to do this is to take the steam from the top of the auxiliary steam header. A steam connection should be provided on each burner for blowing the oil out of the burner when it is shut down, as otherwise this oil will carbonize, due to the heat radiated from the hot furnace.

The principal consideration affecting the efficiency of an oil-burner installation, other than the choice of a burner economical in the use of steam (and giving the proper shape of flame), is the proper control of the air supply. One of the advantages of burning oil, mentioned above, was the possibility of reducing the excess air to effect combustion. Conversely, one of the principal losses is the ease with which excess air can be admitted. For any particular installation (assuming the setting is tight and checkerwork properly arranged), the best draft should be determined by installing a draft gauge on each boiler connected to the furnace, then gradually closing the damper until there appears just a faint trace of black smoke at the stack, and finally maintaining the draft at that point. It should be noted, however, that there can easily be smoke with excess air for two reasons: first, if the checkerwork is not properly arranged in the furnace there will be excess air, even though the combustion be incomplete, and second, poor atomization of the oil at the burner will give a grayish-white smoke, which is often mistaken for insufficient air. A more accurate method of gauging the air supply is to make periodical analyses of the stack gases and keep a record of the stack temperatures. The stack gases should not be over 100 deg. hotter than the steam, and no difficulty should be experienced in getting 13 to 14 per cent. CO_2 in regular operation.

REFRIGERATION DEPARTMENT

SAFETY IN REFRIGERATING PLANTS

THE ever-increasing congestion in our large cities, is one of the most potent of the causes of the rapid development of the artificial ice and refrigeration industry. If a hotel manager a generation ago had been asked to serve fresh vegetables in midwinter, he would have had considerable difficulty in complying with the request; but fresh vegetables are now available at practically all seasons of the year, at a cost within the means of persons in moderate circumstances. This is only one of the many items that have made the refrigerating industry possible, and because of this industry many things that were luxuries a few years ago are now considered to be necessities. Perishable food must be preserved in a suitable condition to provide the necessities of subsistence for the public, and especially for that part of the public that lives in the congested sections of our cities. These persons have neither space nor facilities for preserving large quantities of food stuffs, and must therefore depend on the dealers, both wholesale and retail, for their daily supplies. Under this arrangement the dealers must keep a comparatively large stock constantly at hand, and in order to guard against loss they must have refrigerating plants of their own, or must depend on natural or artificial ice, to maintain their establishments at proper temperatures.

There are in the United States over 12,500 ice-making plants, having an aggregate annual output of about twenty million tons. This does not include the thousands of private refrigerating plants in small restaurants, meat markets, grocery stores, and private dwellings. The principles of artificial refrigeration are being applied in more than 150 different industries, including among others, mining, paper making, woolen and silk manufacturing, laundering, and tobacco manufacturing, says the "Travelers' Standard."

Refrigerating Plant Hazards

As might be expected, an industry in which chemicals and highly-compressed gases are used in connection with tanks, piping, and moving machinery, is not immune from accidents. The growth of the refrigerating industry, employing high-pressure gases with the attendant risk of explosions and other accidents, is attracting the attention of municipal authorities to such an extent that regulations for installing and operating the plants have been drawn up and put into effect in many localities. No doubt these regulations will have to be revised as experience is gained in their application, and in this respect they may be expected to have a history similar to that of analogous regulations applying to steam boilers.

The fact that municipal authorities are taking steps of this kind in connection with the refrigerating industry indicates a growing public appreciation of the importance of the hazards pertaining to it. As in almost every other industry, the majority of the accidents that occur are avoidable, provided sound engineering principles are followed in the design, installation, and operation of the plants. It follows, then, that the engineer who designs the plant, and the man who supervises the installation, should bear in mind the question of safety; and it is equally important to place competent men in charge of the operation of the plants, because the judgment and ability of the men who supervise the work are exceedingly important factors in preventing accidents.

Ammonia Leakage

Leaks in a refrigerating plant usually occur at the gaskets or through cracks in pipes or other defective parts of the apparatus under pressure. Very often such leaks have no other consequences than the loss of a certain amount of ammonia; but when the defect is of such a nature as to allow large quantities of ammonia fumes to escape, more serious results often follow. For example, if there are arc lamps or open flames in the room, or a free connection between it and the boiler room, the mixture of ammonia, hydrogen, and oil-vapor and other volatile impurities may ignite and fill the whole compartment with flame for a short time, with serious consequences to anyone who may be present. The fire hazard from this cause may be practically eliminated by using electric incandescent lamps, and installing self-closing doors between the boiler room and the rooms where leaks are likely to occur.

A leak of sufficient size to quickly fill the engine room with ammonia fumes is exceedingly hazardous to the employees. A very brief exposure to the fumes would be sufficient to overcome persons in the room, and unless immediate assistance were given, death from suffocation would quickly follow. It is essential, then, that the system be arranged in such a way as to permit the employees to shut off the ammonia supply quickly, from any one of three or four widely separated points. In addition to this, oxygen helmets should be distributed about the room at convenient places, so that the employees may procure them quickly in case a leak or rupture accurs. Equipped with these helmets, the men will be immune from the dangers of the fumes for a short time, and will be able to make temporary repairs.

Air Pressure Test

It is customary, when installing a refrigerating system, to test it under air pressure before it is charged with ammonia. This practice is commendable if it is properly carried out; but if it is done in a careless manner, by inexperienced men, it may result disastrously. The principal sources of danger are those due to a break of some defective part of the system, or an explosion brought about by the ignition of oil-vapor or other inflammable impurities. The various parts should be tested by the manufacturer before shipping to the point of installation, and they usually are. Shocks received during transportation or installation may cause a defect in some part of the system, however, and the points may also be poorly made. For these reasons extreme care should be taken to guard the workmen during the test.

It is customary to lubricate the cylinder walls of the compressor with oil before starting the test, and more or less of this oil is forced into the piping by the compressor, and collects in pockets. As the pressure is increased, more and more heat is generated, the oil vaporizes, and if the rise in temperature is sufficient, an explosion results. Lubricating oil having a low chill-point is desirable for regular use in refrigerating plants; but most oils that fulfil this requirement have a low flash-point also, and they are therefore dangerous to use in an air-pressure test. Low chill-point oil is not so essential as high flash-point oil during the test, because the higher the flash-point the less is the danger of explosion.

A thin coating of lard oil should first be applied by hand to the walls of the compressor cylinders, and the compressor allowed to run until the pressure reaches 100 lbs. or more. The compressor should then be stopped long enough to cool down after which it should be started up again and operated until forty or fifty pounds of additional pressure is obtained. It should then be stopped again, and when sufficiently cooled it should once more be started, but at reduced speed, and stopped whenever the discharge pipe becomes hot enough to be uncomfortable to the hand. If these precautions are taken there is little chance of an explosion from internal causes during the test. The men should be kept away from the apparatus as much as possible, however, as

there is always a possibility that an accident may occur through the failure of an imperfect joint, or from unforeseen weakness in some other part.

Pipes less than two inches in diameter should not be used, except in single lengths. Pipes of smaller size than this are usually butt-welded, and are bent to the desired shape instead of being made up with fittings; and it should be remembered that there is always a possibility than an imperfect weld or an imperceptible crack will open during the bending process, when long pipes of small diameter are used—particularly if the bend is at or near the weld. No matter what size of pipe is used, it should be properly supported, and should be installed so that it will not be subject to shocks from any source whatever.

Operation Carelessness

Carelessness is just as dangerous in a refrigerating plant as in other industries. An operating engineer who neglects to open the valve in the pipe connecting the charging pipe and the shipping tank containing the ammonia, at charging time, shows gross carelessness, and a man of this type is likely to hasten the charging operation by applying hot water or steam to the shipping drums. Naturally, the heat thus furnished will increase the pressure in the drum to which it is applied, and if the valve is closed there is no means of relieving the extra pressure except by an explosion.

At this point it is well to call attention to the great importance of keeping all valves in the plant in good operating condition. There are many valves in a refrigerating plant that are seldom used. The mere fact of their presence indicates that they have been installed for some purpose, but their usefulness is questionable (or, rather their uselessness is a certainty) if they are not regularly inspected and tested. Rust in the stuffing-box gland and on the threads of the packing nut is a common source of trouble in a plant. The greater the accumulation of rust and the longer it remains, the harder it is to operate the valves; and when occasion arises to use them, after a period of neglect, it is often found that they act as if they were solidly cast in the piping.

Compressor Accident Classification

Compressor accidents may be divided into two classes: (1) those due to the breaking of some part of the compressor itself, and (2) those occasioned by conditions not inherent in the construction of the machine, such as unusual pressures, explosions, or the presence of liquid ammonia in the compressor. Accidents under the first class include the breaking of valves, piston rods, and rings, or the rupturing of cylinder walls and heads. Valve breakage is the most frequent cause of compressor accidents, and is due principally to unnecessary wear, improper cushioning, or deterioration of the metal. It is evident that careful attention to the materials of construction, and to the design and installation, are necessary in order to keep accidents of this class at a minimum. Accidents due to the rupturing of cylinder walls and heads are rare, and are usually attributable to faulty design and construction, or to a lack of proper consideration of shrinkage strains. Piston rings formerly caused considerable trouble, but ordinary snap rings are now used with satisfactory results, so far as accidents from this cause are concerned.

Accidents under the second heading are not very frequent, but they are likely to be much more disastrous. Those caused by excessive pressure may be avoided in considerable degree by requiring ample safety factors in the material, design, and construction of compressors. In addition to this, relief valves should be so installed that they will operate before an increasing pressure has reached the limit of safety. The discharge valve may accidentally be left closed and the machine started, and unless a relief valve has been installed it is certain that as the pressure increases something must give way. If a relief valve is installed in a by-pass, or in a connection made between the discharge-side pipe of the compressor in front of the stop-valve and the suction side of the compressor in front of the suction stop-valve, protection will be given against excessive pressure in the system as well as in the compressor.

However, carefully a system is designed and installed, a certain amount of liquid is likely to accumulate, and its presence in the compressor is always a source of danger. The obvious remedy is to provide a properly located relief valve, of sufficient capacity to permit the discharge of practically all the liquid present before the piston reaches the end of its stroke. There are cases where considerable difficulty may be experienced in equipping compressors with such devices, but the greater safety gained is well worth the trouble.

Every steam engine should be provided with a safety stop, wholly independent of the ordinary governor. In case the governor fails to work properly and the engine starts to "race," the independent safety stop is supposed to operate as soon as the speed exceeds a predetermined limit, shutting off the steam, bringing the engine to a standstill, and preventing the bursting of the flywheel and other serious consequences.

The operating engineer of a refrigerating plant should remember that he is subject to many of the hazards that are to be found in the ordinary power plant, and also to some additional ones. For example, in compressing air he should never use a machine that has recently been used to compress ammonia; and in opening gauge cocks he should stand at the side rather than in front of the gauge glasses. Such precautions as standing at the side rather than in front of cylinders or compressors, and refraining from calking pipes or tightening up fittings while they are under pressure, are generally understood, but often disregarded. It is particularly dangerous to calk joints or tighten nuts or fittings under pressure. Many fatal accidents have been caused in this way.

In the growth of any industry, dangerous situations arise that could not possibly be foreseen. This is one of the penalties of pioneer work. We have commented on some of the more common hazards in the refrigerating industry. No doubt as the industry grows, new conditions, some of them having considerable elements of danger, will arise. Refrigerating engineers should have this possibility in mind at all times, and by calling on past experience endeavor to keep down the number of unforeseen dangers.

HIGH SPEED AMMONIA COMPRESSORS

IN the March issue of the Journal of the American Society of Refrigerating Engineers, C. R. Neeson discusses the the reason for using high speed ammonia compressors, also the main features of their design. In regard to the latter he states that the only type of valve feasible is one consisting of a thin plate of special steel to cover a series of slots in the valve cage, which gives a maximum opening with a very small lift, thus allowing a rapid movement of the valve without shock or noise. As the valves must be accessible they are placed radially in the cylinder body at each end, suction valves at the top and discharge valves at the bottom. All valves are alike and interchangeable.

A new principle has been adopted in order to completely fill the cylinder to suction-pipe pressure. This consists of a series of ports around the centre of the cylinder casting which are uncovered by the piston at the end of the suction stroke when its speed is least and its acceleration greatest, and where the inertia of the gas in the suction pipe tends to build up the pressure at the cylinder. The length of the piston is about the same as its stroke. As there are no valve springs to overcome, it is possible in spite of the so-called high speed to fill the cylinder to the exact pressure in the suction line. Several diagrams exhibited go to prove this statement. These diagrams show that the pressure in the suction pipe at the beginning of the suction stroke is slightly above the pressure at accumulator, due to the inertia of a column of gas at high velocity which is stopped suddenly when the piston reaches the end of the stroke closing the suction valves.

Castor Oil.—A few years ago castor oil was the universal lubricant for both internal and external lubrication, but as engineers became more enlightened on the subject generally, for internal lubrication it was discarded. The principal reason why castor oil has been condemned for internal lubrication is the breaking up of the oil into several corroding acids when exposed to high temperatures. As a lubricant for external bearings, however, castor oil is still largely used, and the old school of mechanical engineers will not listen to anything against it.

Power House Plant and Equipment for Engineering Works

Staff Article

The provision of suitable power, light, heating and similar systems in a shop engaged in modern engineering work calls for a diversified equipment, each item of which must be capable of rendering satisfactory service day in and day out. It is a matter of interest to readers that so much of the equipment installed should be the output of a single firm.

AS builders of high-grade machinery products, the Goldie & McCulloch Co., Galt, Ont., has enjoyed an enviable reputation for sixty-eight years. As a firm, therefore, two of whose principal lines are engines and boilers, it was to be expected that they would generate their own power, light and heat, despite the possible economy attaching to the use of Hydro-Electric power and its great development in that part of Ontario surrounding the City of Galt. On the other hand, the installation of a complete power plant may be looked on as evidence of confidence in one's own product, with its opportunity for observation, experiment and improvement unhampered by any considerations save those pertaining to the operation of the works as a whole.

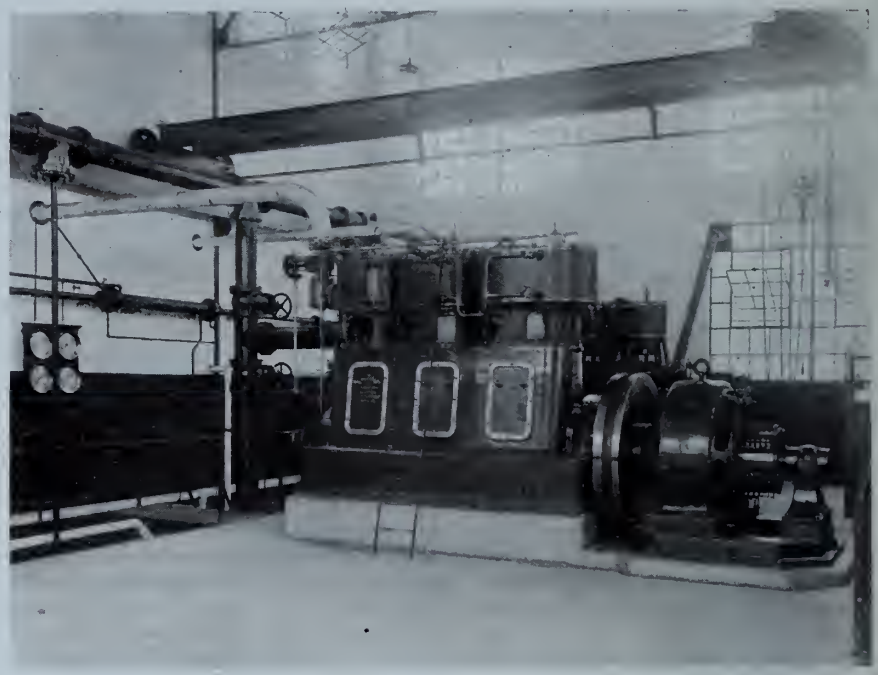

FIG. 2. 300 HORSE-POWER VERTICAL ENCLOSED ENGINE WITH WESTINGHOUSE D. C. GENERATOR.

Equipped With Own Product

The power house which forms the subject of this article has just been recently completed and is situated at the Co.'s South Works, giving the necessary service of electric power and light, steam power, pneumatic power and hot water heating. The entire installation, with the exception of minor accessory equipment, is the product of the firm's own shops and possesses peculiar interest thereby. which increases with a close study of the plant.

A side elevation of the plant is given in Fig. 3, which shows the principal features of the building, and the relative arrangement of the various items. A plan view is reproduced in Fig. 4, while a side elevation of the pump room, engine room piping and heaters is given in Fig. 7. The building is approximately 105 ft. by 60 ft., and is of steel and brick construction, the boiler room and bunkers being sunk 9 ft. 6 in. below the level of the engine room, an arrangement which facilitates the projection of the engine room roof above that of the boiler room, giving a semi-monitor effect which allows of light being received from all four walls of the engine room. The roof trusses are of steel construction supported by I beam columns, the latter being entirely built in with brickwork and hidden from view so that the interior effect produced is particularly pleasing, especially in the engine room, surrounded by a dark green dado extending 6 ft. up from the floor level, with white throughout above.

FIG. 1. "G. & McC." WATER TUBE BOILER, SHOWING MECHANICAL STOKERS, SOOT BLOWERS AND ASH-HANDLING EQUIPMENT.

Arrangement of Building

Three main divisions are formed in the building,—coal bunker, boiler room and engine room. The coal bunker is at the left of the illustration and is supplied from hopper bottom cars, the tracks for which are level with the ground outside. A spur line from the C.P.R. enables the cars to be brought conveniently to the building, the bunkers having a capacity of approximately three carloads in addition to one on the tracks.

Boiler Room

The boiler room is laid out so as to have ultimately four G. & McC. water tube boilers with a total capacity of 1,280 horse-power. At present two boilers of 320 horse-power each are installed, De-

troit mechanical stokers being fitted to each. Spanning the stoke-hold floor and of sufficient height as shown, is a small hand traveling crane with electric hoist and dumping bottom truck. By this means the coal is readily transferred from the bunker to the hoppers on top of the stokers, the ashes being elevated by the same device and deposited in a team wagon run in on a platform next the wall.

ous headers having easy curves to avoid any retardation of circulation. The parts of the boiler subjected to pressure are of forged steel throughout, the design, material and workmanship placing it on an equal footing with best types of boilers made in other countries.

sions. A steam driven Sheldon fan draws the hot gases through a smoke breeching between the boilers and the division wall, the fan being driven by a G. & McC. horizontal high-speed Ideal

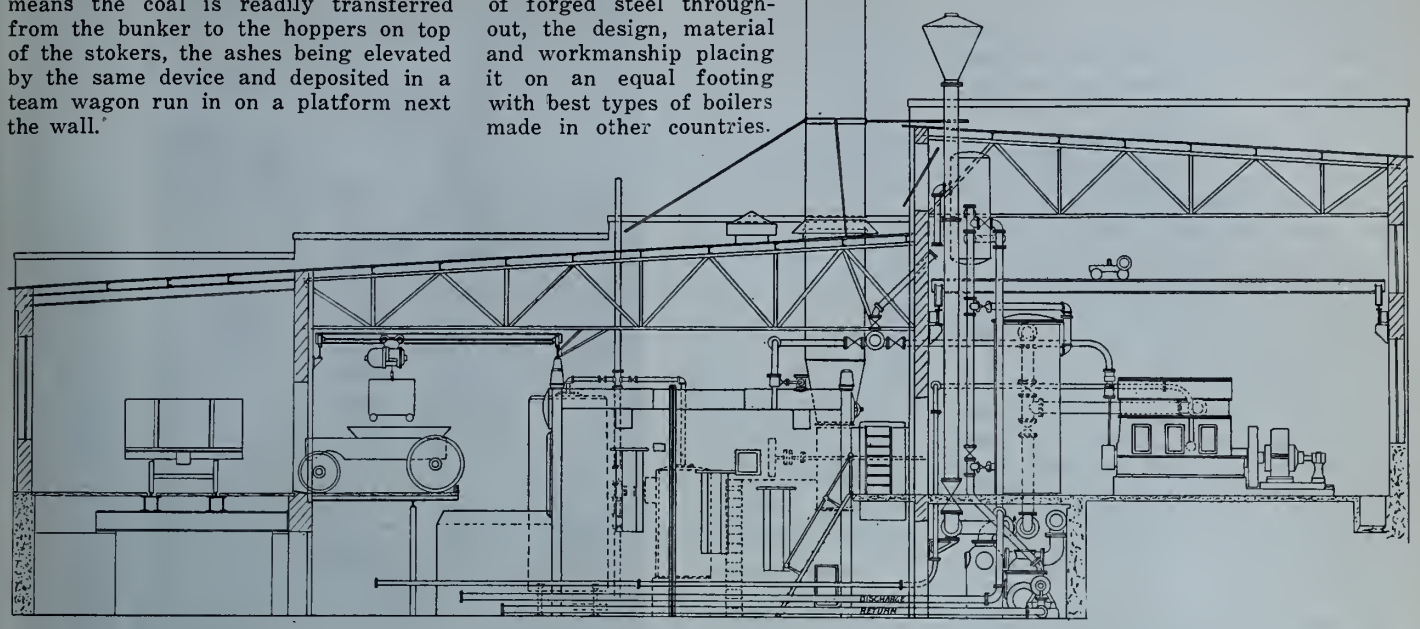

FIG. 3. SIDE ELEVATION OF POWER PLANT BUILDING SHOWING ARRANGEMENT OF VARIOUS UNITS.

Water Tube Boilers

The water tube boilers are of the Goldie & McCulloch sectional type which resembles in general appearance the ordinary type of sectional boiler, but which is provided with such important details as extra size nipples and rear circulating tubes, together with large sinu-

The working pressure of the boilers is 175 lbs. per sq. in. and G. & McC. superheaters of forged steel construction are fitted, a temperature of 530 degrees Fahr. being continuously available.

Induced draft gives ample control over combustion conditions and permits the use of a steel stack of moderate dimen-

engine. Access to the fan platform is had by a stepladder direct from the boiler room floor, and also by a stepladder from the engine room floor level along a gangway on top of the smoke breeching. This gangway also provides convenient access to the steam and super-heater valves.

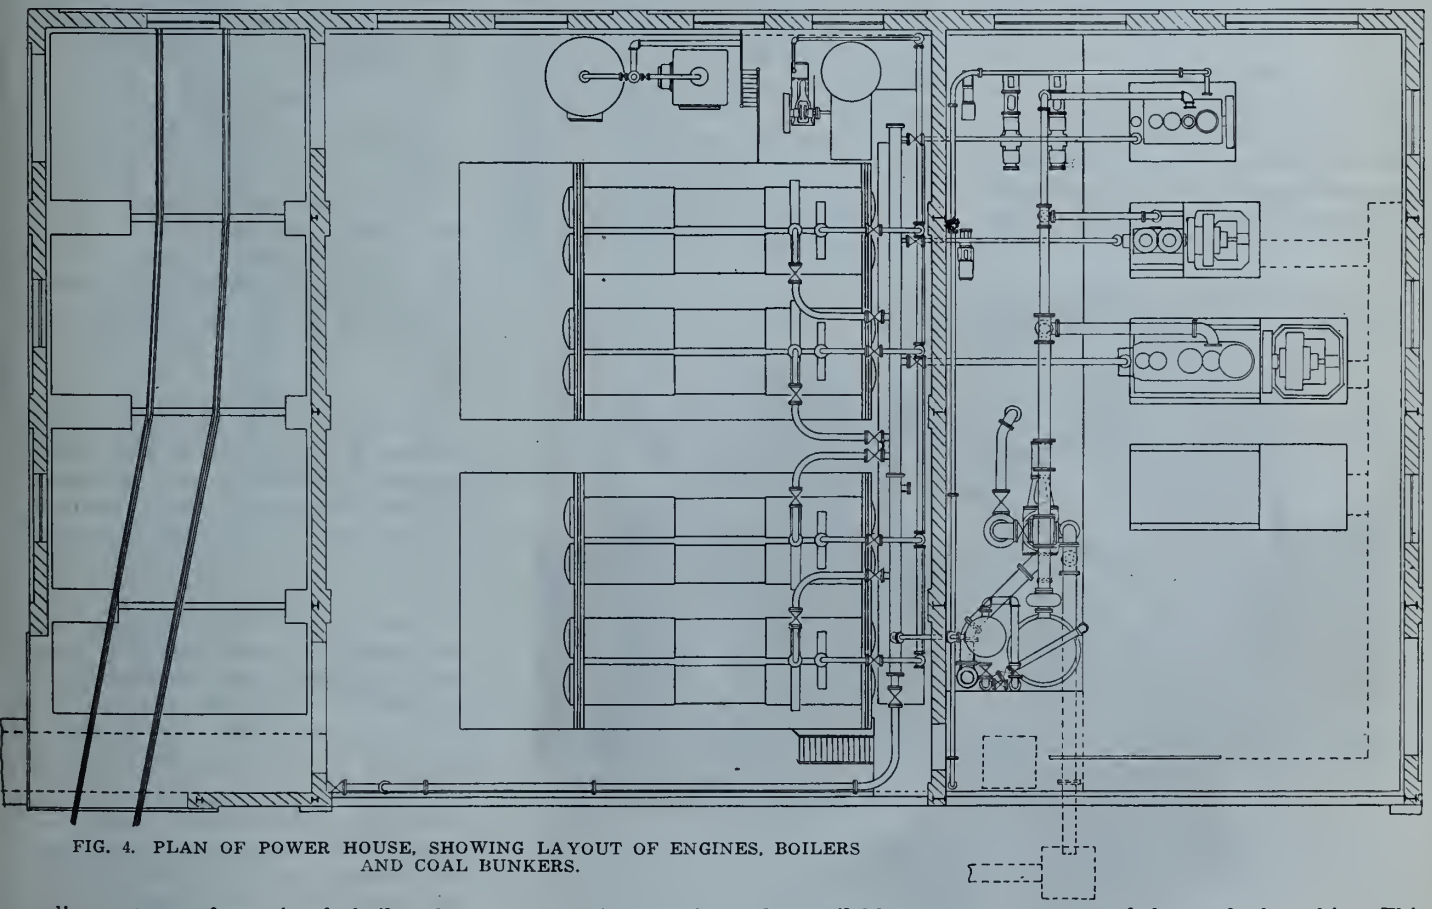

FIG. 4. PLAN OF POWER HOUSE, SHOWING LAYOUT OF ENGINES, BOILERS AND COAL BUNKERS.

Complete Valve Installation

A feature of the pipe arrangement is the very complete installation of valves to insure the utmost degree of control and safety, both under normal operating conditions and in case of accident. On the steam pipe from each boiler is an automatic isolating valve which closes in the case of a burst pipe or other emergency. Hopkinson-Ferranti stop valves are installed on the main and engine pipe lines, the isolating valves being also of Hopkinson manufacture. All of these valves, which are made in England, have cast steel bodies with valves and seats of "platnam" metal, and, together with their manner of installation, represent the most recent power plant practice. The steam header is extra heavy steel pipe with solid welded nozzles—made by the Walworth Co.

A result of careful designing of the piping is the entire absence of leaks even of minor proportions, this being due both to careful erection and the use of suitable packing to withstand the pressure and super-heat temperature; Calore packing is used exclusively throughout.

As shown in plan drawing Fig. 4, the boiler room occupies the main central part of the building, being 46 ft. wide. At the lower left hand corner of the boiler room, and passing across the end of the coal bunker, is a tunnel, 7 ft. high by 4 ft. 6 in. wide, through which pass all the service pipes and wires to the various factory buildings.

Water Supply

The ground on which the building is erected was underlain with solid rock, and the boiler room, pump room, bunker space and tunnel were excavated from this material. At the same time a boring was made in the pump room to a depth of 240 ft., from which water of excellent quality and low temperature is obtained in ample quantity. This water is used for boiler feed purposes, and is passed through an Ideal feed water heater of G. & McC make, an auxiliary heater of square form being installed alongside. As an addition to the purifying treatment to which the feed water is subjected in the heater, Perolin boiler compound is used, the internal condition of the boilers, due to the use of this preparation, being entirely satisfactory. Diamond soot blowers and Everlasting blow-off valves complete the accessory equipment.

FIG. 6. VIEW OF PUMP WELL LOOKING DOWN ON CONDENSER.

Engine Room

The engine room, as will be gathered from the line drawings and also interior view, Fig. 2, is particularly spacious, having a width of 35 ft. and occupying the entire right hand portion of the building. In the upper part of Fig. 2 can be seen the hinged glasslights which open above the roof of the boiler room, while the other sides are liberally provided with steel sash lights with ventilating sections. Repair and erection work is rendered easy by the installation of a 5-ton Herbert Morris overhead traveling crane.

Two electrical generating units and one air compressor are at present installed, with space sufficient to allow of more than doubling the present capacity. All of these units are steam driven, and run condensing.

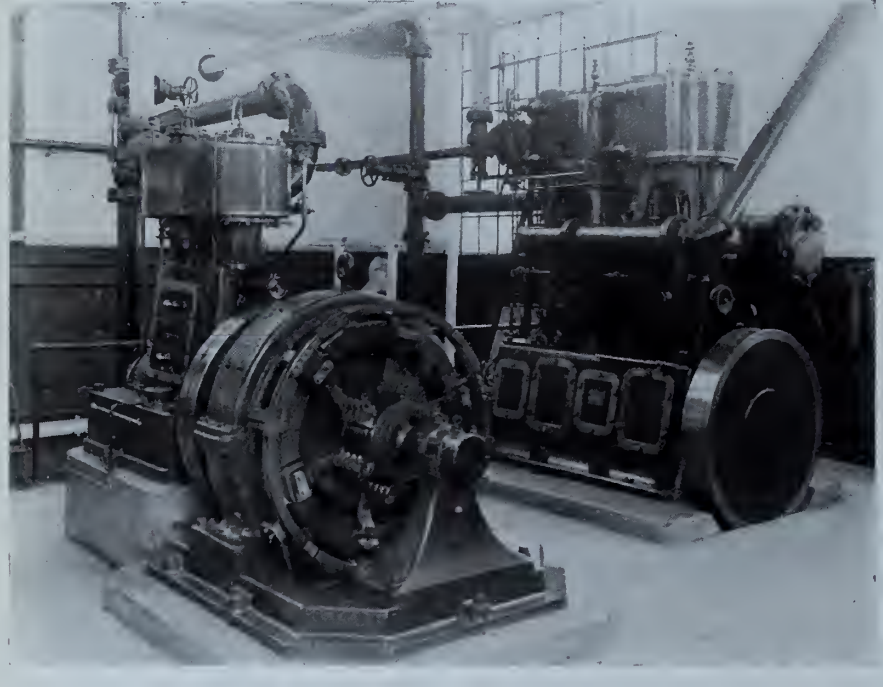

FIG. 5. SMALL POWER UNIT AND TWO-STAGE COMPOUND STEAM-DRIVEN AIR COMPRESSOR.

Main Unit

The main unit, see Fig. 2, consists of a Goldie & McCulloch triple expansion, vertical enclosed engine of the quick-revolution type, having forced lubrication. The cylinders are 12 x 17 x 25 in. dia. by 10 in. stroke, giving 300 brake horse-power with an overload capacity of 25 per cent. This unit is direct connected to a 200 k.w. Westinghouse d.c. generator and carries the main shop load.

The smaller unit consists of a compound engine of similar type, having cylinders 9 x 15 in. dia. by 7 in. stroke, running at 450 revs. per min., and giving 150 brake horse-power, with 25 per cent. overload capacity. It is direct connected to a 100 k.w. Westinghouse d.c. generator, and is used for night work, light loads, and as an auxiliary during heavy overload periods. The governing system employed on these engines is of the combined throttle and expansion type, and McCord lubricators are used for oiling the cylinders. Both engines are standard sizes as regularly produced by the builders and represent the highest development of the marine type as adapted to land conditions, their manufacture having been undertaken so as to keep pace with the rapid development of electrical machinery and the increasing demand for higher speeds and pressures. The forced lubrication system referred to is an outstanding feature of the design, every

bearing and pin, even to the governor pins, being fed with oil under a pressure of 15 to 20 lbs. per sq. in., all dust and dirt being absolutely excluded by the construction employed. Their operation is characterized by an absence of wear even over a period of years; they require a minimum of attention, are neat and compact in appearance, silent and practically vibrationless in running.

Air Compressor

Fig. 5 illustrates the smaller unit and also the air compressor. This latter machine is built by Alley & McLellan, Glasgow, Scotland, and is of the steam driven, vertical straight line type, the air cylinders being immediately above the crank case, with the steam cylinders above them. Compound expansion is used in the steam cylinders. The air intake pipe can be observed coming down from the engine room wall and passing along the side of the air cylinders, which operate on the two-stage system, air being drawn in on one side of pistons at atmospheric pressure and discharged into the intermediate receiver, the end of which can be seen in the illustration, from which it passes to the high pressure side of the same pistons and thence at 100 lbs. pressure to the air main which passes through the tunnel to the shop. The compressor operates at a speed of 300 revs. per min. and at this speed has a capacity of 650 cubic ft. per min.

When operating at slow speeds with an output less than its capacity, the compressor is controlled by a governor operated by pressure from the air main, acting on a relay piston in a cylinder carried by the main governor lever. When maximum demand and pressure is required, the main governor lever comes into operation in such a way that the relay piston is rendered inoperative and governing is direct from the crankshaft; this condition also obtains in the case of accident to piping, etc., which otherwise would let the compressor run away.

Condensing Plant

The condensing and heating systems will be understood by referring more particularly to line drawing Fig. 7, which also shows the boiler feed pumps and, at the left, the intercepting tank into which the condenser discharge is conducted. Two main exhaust pipes are provided extending horizontally as shown and into either of which one or all of the units can be made to exhaust as required. The lower pipe passes directly to a 1,000 horse-power standard G. & M. type of pet condenser, located close to the well and within a few feet of the same level as the water. This allows the water easy access to the condenser which maintains a vacuum of 26 in. in summer without difficulty. The level of the water in the well rises after rain to a height of 2 ft. above the floor, at which point it has very little further rise to make to enter the condenser.

The upper exhaust main passes through a Sheldon oil separator and enters a large tubular heater of the vertical cylindrical type from the bottom of which a pipe leads back to the condenser. An atmospheric exhaust is also provided for by a branch pipe from the lower exhaust main, running into the vertical exhaust pipe shown with exhaust head on top.

Shop Heating System

During the winter months the works are heated on the Evans hot water system, the water being heated by exhaust steam from the engines in the heater just referred to. The temperature is regulated to weather conditions by reducing the flow of exhaust steam to the condenser, thereby shunting the required amount of steam round through the heater. In winter weather a vacuum of 26 in. is obtained between the regulating valve and the condenser, with a varying vacuum in the heater, according to requirements. A table giving the proper degrees of vacuum to be maintained in the heater, according to weather conditions, is supplied to the engineer, who works accordingly.

Situated above this heater is a small auxiliary heater arranged to be operated with live steam from the boilers; this is used over week-ends, holidays and on such occasions as there is not sufficient exhaust steam available.

The hot water is circulated by a turbine driven centrifugal pump immediately below the main heater, the turbine being of G. & McC. manufacture, direct connected to a Rees-Roturbo pump made Manistee, Mich.

Pump Installation

Part of the pump room is shown in Fig. 6. The remaining equipment here in addition to the condenser and turbine pumps consists of duplicate sets of Goldie & McCulloch simplex boiler feed pumps, 12 x 8 x 12 in. of the outside centre packed plunger type, arranged to draw either from the hot well or direct from the artesian well. Also one piston pump of same make 8 x 5 x 10 in. which can be used for boiler feeding, and one service pump 8 x 5 x 10 in. which supplies cold water from the bore hole for drinking, washing and lavatory purposes.

Fire doors are provided between the various sections of the power house and sprinklers are installed in all locations where their use is desirable.

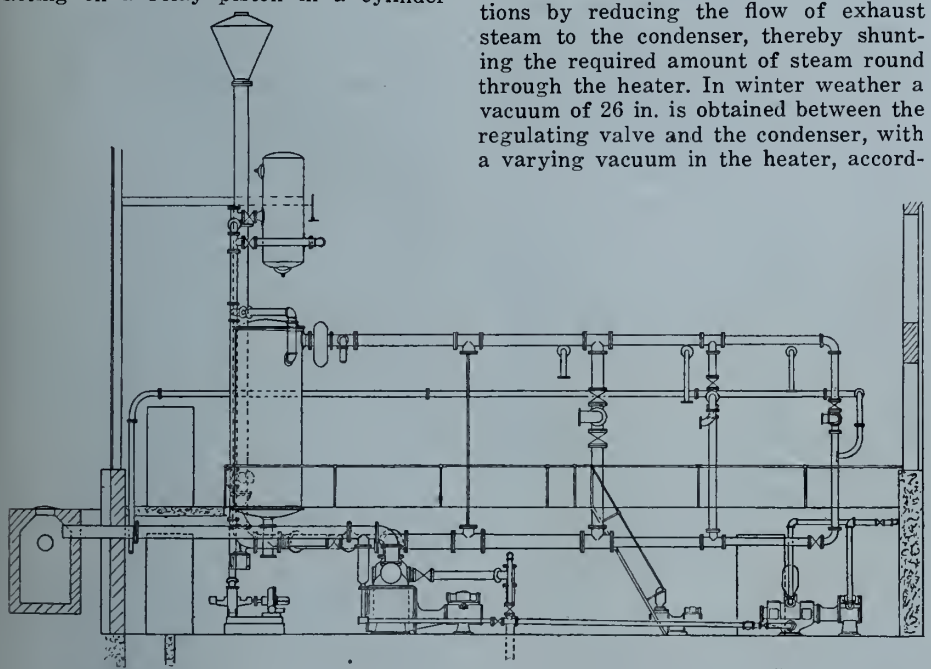

FIG. 7. ELEVATION OF PIPING, CONDENSING AND HEATING SYSTEMS.

BOILER SERVICE MAINTENANCE

A BOILER is in a dangerous condition when the plates, bolts, braces or rivets of which it is constructed become weakened to such an extent that the internal force or pressure equals the tensile strength of the material at the weakest section or sections. In this condition, strains due to varying temperature will cause rupture and an explosion, the volume and destructiveness of which would be in accordance with the size of the boiler and the pressure carried therein.

The moment a boiler is placed in service it gradually becomes weaker, due to the destroying forces continually acting upon it. These forces are of both a chemical and mechanical nature. Corrosion and oxidation are continually acting on the material from which a boiler is constructed, and take place both internally and externally, these processes being the two most serious and subtle causes of weakening to which a boiler is subjected. Evidences of these are most noticeable in the grooving and pitting of plate, and more especially at locations most subject to deposits of mud, scale and organic substances.

Expansion and contraction also play a very important part in the destruction and weakening of a boiler, more especially when concentrated at any one point, such as at sharp bends or flanges in the plates where the inner and outer sheets are subjected to different temperatures. Constant working or bending of bolts, flanges or angles, however slight, will sooner or later destroy the fibres in the material at points subjected to it, causing crystalization, cracking, and leaving same more susceptible to the chemical action of the feed water.

It is therefore obvious that only thorough examination by competent inspectors who understand the construction, nature of defects, and remedies to be applied, will maintain a steam boiler in safe working condition.

Electricity and Hydraulics

PLAYING HOSE STREAMS ON CHARGED ELECTRIC WIRES

FROM the earliest days of the adaptation of electricity to commercial purposes there has been, says *The Travelers Standard*, a more or less hazy notion that turning a stream of water on a live wire is a highly dangerous proceeding. Only a few years ago the statement was frequently made in the newspapers that firemen were hampered in their efforts to control a fire because of their fear of directing a stream of water on a high-tension circuit. Such a notice appearing in a paper to-day would reflect on the efficiency and standing of the particular fire department referred to. A study of the question has been made, with the result that every modern fire department has the necessary equipment to protect the firemen from shock. This equipment is in the form of rubber gloves and boots, insulated handles on the nozzles, a marline covering over all hose connections, or other equally effective insulating devices.

Probably the most authentic information on this subject may be had from the records of the fire departments in the principal cities in the United States. These fail to show that any fatal or even serious injury has been caused by directing a hose stream against a high-tension circuit, although a number of departments report that slight shocks have been felt by hosemen. This excellent record is accounted for in part by the fact that overhead circuits are seldom found having pressures above 30,000 volts, within the territory of the fire departments.

Hazard Determination Tests

The Pennsylvania Railroad Co. carried out a series of tests to determine the hazard involved in directing a stream of water on to a high-tension line. Three circuits were available for the purpose—one direct-current circuit of 525 volts pressure, one alternating-current circuit of 2,300 volts, and one of 4,600 volts pressure. Solid streams of fresh water from ⅝-inch and 1-inch nozzles were played on these circuits from various distances, and the difference in potential between the nozzle and the ground was measured by a voltmeter. The summarized results of these tests are shown in Tables 1 and 2. From these tables it is evident that a person standing ten feet away from circuits of the above-mentioned potentials runs no great risk of dangerous shock.

Table 1.—Voltage to Ground from a Five-eighths-inch Nozzle

Voltage on wire.	Distance from nozzle to wire.	Volts between nozzle and ground.
525 (D.C.)	7 ft. 5 in.	20
525 "	4 ft. 9 in.	38
525 "	3 ft. 7½ in.	60
525 "	2 ft. 2 in.	70
525 "	0 ft. 7½ in.	210
2050 (A.C.)	6 ft. 6½ in.	Static
2050 "	3 ft. 5½ in.	Static
4100 "	6 ft. 6¼ in.	Static
4000 "	3 ft. 5½ in.	Static

Table 2.—Results of Demonstration at Altoona.

Size of Nozzle	Voltage on Wire	Distance from Nozzle to wire (Feet)	Volts between nozzle and ground
⅝ in.	525 (D.C.)	3	Slight indications of static electricity to the hand
1 in.	2300 (A.C.)	8	Slight indications of static electricity to the hand
1 in.	4600 (A.C.)	10	Slight indications of static electricity to the hand

An important point brought out in connection with these tests is the fact that playing a solid stream from a hand chemical extinguisher on a high-potential circuit is an extremely dangerous proceeding. The difference in potential between the nozzle of a chemical extinguisher and the ground is approximately seventy-five per cent. of the difference between the line itself and the ground, provided the nozzle is held nine or ten inches from the circuit. Assuming a circuit of 3,000 volts and a nozzle ten inches away, the person holding the extinguisher would be subject to a shock from a potential of approximately 2,000 volts. It seems, then, that the stream from a chemical extinguisher does not offer the same resistance to an electrical current; or in other words, it is a better conductor than fresh water.

With nozzles of larger diameters and circuits of higher potentials the resistivity of the water largely determines the hazard to the men directing the stream. This fact was brought out by a series of tests made at Ohio State University, in which use was made of potentials ranging from 5,000 to 30,000 volts. Nozzles 1½ inches and 1⅛ inches in diameter were used, these being the two sizes generally employed by fire departments.

Increased Water Pressure Increases Resistance

One of the important points determined by these tests is the fact that an increase of water pressure increases the resistance, because it tends to cause the stream to break up at a shorter distance from the nozzle than when a lower pressure is employed. As the solid stream breaks up into separate drops the resistance rises suddenly, thus preventing the flow of electric current in dangerous potentials. It was found that with a 1⅛-inch nozzle the solid stream began to break up after travelling 15 to 17 feet, according to the water pressure, and with a 1½-inch nozzle after it had travelled 20 feet. This shows that for safety when playing streams on circuits above 5,000 volts, the hosemen, using 1⅛-inch or 1½-inch nozzles, should stand at least 20 or 25 feet respectively from the wires; and, in addition, at these distances all modern insulating precautions should be observed.

Overhead high-tension circuits within the fire department limits or near buildings are carried on poles 25 to 40 feet high, so that there is little danger that the firemen while standing on the ground will receive shocks through the streams of water directed on the circuits. Modern fire-fighting apparatus, however, includes metal ladders and extension towers, and it is quite possible for firemen working from either a ladder or a tower, to unintentionally bring the nozzle close enough to a high-tension circuit to receive a serious or fatal shock.

ELECTRICAL DRIVE FOR ROLLING MILLS

By O. C.

THE driving of rolling mills is one of the most difficult problems the electrical engineer has been called upon to solve. He has accomplished it quite successfully in a number of cases. The problem was an exceedingly difficult one even for the steam engineer; and the difficulty arises from the very quickly changing character of the load. Before the billet is entered between the rolls the only work the steam engine or the motor has to perform is the very trifling amount required to turn the rolls, along with the engine or the motor itself; immediately the rolls take hold of the billet the power rises to a maximum, which may be several hundred or several thousand horse power, according to the size of the rolls and the character of the work they have to perform. Immediately the billet emerges from the rolls on the other side, the whole of the power previously absorbed is set free, the engine or the motor now being required to furnish only the trifling power absorbed by the friction of the apparatus itself. The period of rest, however, as is well known, is very short, only sufficient to allow of the billet being re-entered between the rolls for the return pass; and immediately it is again entered and the rolls have gripped it, the power rises to a maximum, though usually not quite so high as the first pass; and this alternate no-load and full-load goes on until the billet has made all its passes; the power required being less at each pass, but being required each time for a longer period.

The first difficulty that confronted engineers in solving the problem was the question of meeting the requirements of the generating station. It is a very serious matter for any generating station to have sudden demands for very large currents, and still more for the station to be subject to the violent fluctuations of these demands. Most generating stations impose a limit upon power customers of the amount of current they may call for at any instant; and the reason is the outflow of a very large current from the generating station at any instant, lowers the pressure of the supply service for the time until the devices provided for meeting increased demand have time to operate. With the increased demand for current for power purposes, central station engineers have been gradually able to keep the lighting service free of the power service, and so they are able to allow larger calls on the power service than previously. But even where the power service is independent of the lighting service, the demand resulting from the insertion of a billet in the rolls of a large mill, would seriously lower the pressure of the service to all the other motors.

With modern methods of electric power distribution also over large areas by the aid of three phase alternating currents, heavy demands for current lead to somewhat serious induction troubles. The difficulty has been met in the same manner as with the colliery winding engine; in fact, the apparatus employed for driving rolling mills is a development of the electric winding engine. The fly-wheel again performs the useful office of absorbing the power that would be running to waste in the intervals between the different passes, and giving it out to aid the current taken from the service during the heavy starting and acceleration period. The interposition of the fly-wheel protects the electric supply service from the heavy demand that would otherwise be made upon it during the early portion of each pass. The full power released by the emergence of the billet from the rolls is not available to assist during the starting period, and therefore the economy to the user will not be so great as if he were allowed to take all the current he required directly from the service. On the other hand, if a central station did allow such an arrangement, it would be obliged to make higher charge for the current, and the cable employed to deliver the current to the rolling mills would require to be very large, or there would be a considerable lowering of the pressure at the motor, in addition to which, the drive would not run as sweetly as it does under existing arrangements.

NEW METHOD OF ARTIFICIALLY LOADING GENERATORS FOR TEST.

IN making tests on hydro-electric plants, it is quite frequently found necessary to provide artificial loads for the generators, says a writer in *The General Electric Review*. In such cases it has been the general practice to use a liquid rheostat formed by placing the electrodes in either the forebay or the tailrace, according to convenience, or sometimes in

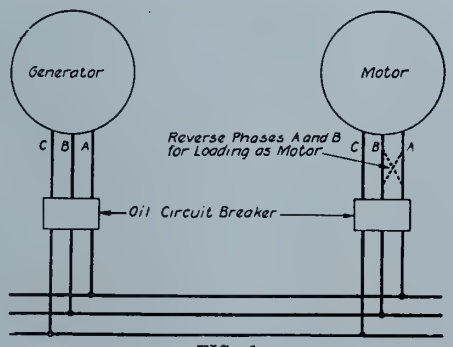

FIG. 1

a special tank with salt solution. Such an apparatus, besides having numerous troubles of its own, produces only a unity power-factor load; whereas the majority of generators are designed for operation at about 0.8 power-factor.

A scheme free from the objections to the liquid rheostat method was first made public in a paper on the Huronian Co. Power Development by Robert A. Ross and Henry Holgate, read before a joint meeting of the Mechanical and Electrical Sections of the Canadian Society of Civil Engineers, April 25, 1907. Since then the method has been used a number of times in various tests by R. A. Ross & Co., consulting and supervising engineers, of Montreal. Through the courtesy of J. Norman Smith, chief engineer of that company, the writer has been given the most important details from its experience; and these are now published for the benefit of any who may desire to use this method.

This same scheme was independently originated and successfully used by O. H. Ensign, Chief Engineer of the United States Reclamation Service, in testing the generators at the Cross Cut Hydro-electric Station, Salt River Project. With these exceptions, this method of loading generators does not seem to be as generally known as its merits justify.

The scheme is exceedingly simple, and consists merely in connecting another generator (when one is available), to the machine under test, with one phase reversed, so that the load generator runs in the opposite direction of rotation as a synchronous motor. When both machines are up to speed and are excited to full voltage, the gates of the wheel which is motoring are gradually opened until the required load is obtained, the wheel in this case acting as a water brake. The generator and motor fields may now be varied to produce any power-factor and voltage desired.

The following instructions prepared by R. A. Ross & Co. for the guidance of their men are of interest:

Instructions for Running Water-Wheel Generator-Motor Test

1—Transpose any two legs of the motor leads (this will reverse the direction of rotation of the motor; see Fig. 1. Say place B in A and A in B on the motor leads).

2—Close the main generator switches connecting the generator and the motor electrically together.

3—Excite both the generator and the motor.

4—Admit water to the generator wheel only, until both machines are turning over.

5—Note that the motor is operating in the reverse direction to that which it would operate as a generator.

6—Raise the voltage and the speed of the generator to normal by operating its field rheostat and by admitting water to the generator wheel.

7—Admit water slowly to the motor water-wheel to act as a brake, as required, to secure any desired load on the generator up to its wheel capacity.

8—Vary the field excitation on the generator and the motor to secure any desired power-factor.

9—The generator instruments will indicate the output of the generator; the instruments on the motor need not be taken into consideration.

10—If the exciters are directly connected to each generator and one exciter is not sufficient to excite the two machines, it will be necessary to reverse the exciter connection on the motor ex-

citer to suit the reversal of direction of rotation.

11—The governor mechanism should be disconnected from the motor, as it might be damaged by reversal of rotation, but an operator should be in attendance, to shut off the water to this wheel, in case of the circuit opening to the motor, when the water passing into the motor water-wheel would stop same, and reverse direction of rotation, causing it to speed up rapidly and possibly run away.

12—By actual operating conditions it has been found that quite a small gate opening on the motor water-wheel is all that is necessary to produce full load on the generator under test.

Troubles Experienced

A few of the troubles experienced by others are noteworthy. One most important point is to have the draught tube of the motoring unit filled with water before attempting to start; otherwise the hunting and surges set up by the wheel revolving against a load which is intermittent rather than steady may trip the oil circuit-breakers, or cause the machine to break from synchronism. On starting, the motoring unit cannot be started from its own wheel, as it would then run in the wrong direction. Usually two duplicate machines can be started together from rest, as described in the foregoing instructions; viz., by exciting both fields, connecting the armatures together, and admitting water to the generator wheel until it starts. The low-frequency currents produced in the generator armature will then drag along the field of the motoring unit and the two machines will run in synchronism from the start.

Trouble may occasionally be encountered due to high static friction in the bearing of one or both machines. This would necessitate opening the generator wheel-gate so wide, in order to "break it from rest," that the resultant large amount of water would cause the generator to accelerate too rapidly and it would break from synchronism with the motor. This may be overcome, in some cases, by starting the machine as a plain induction motor; i.e., by not exciting the motor field until it is partly up to speed. If this is not successful, the gates of both units may be opend just enough to start them turning over, without switching them together. As soon as the units start revolving, the gates should be closed and field applied to whichever unit is necessary to make them come to rest at the same instant. Just before they stop they should be switched together, fields applied to both machines, and the generator gate opened until they start together. This procedure will eliminate the high static bearing friction and no difficulty should then be experienced in geting started.

It is doubtful if much trouble will be encountered with horizontal units; but vertical machines, especially those equipped with Kingsbury or plate-type thrust bearings, are likely to be obstinate. It should be particularly noted that Kingsbury bearings are usually designed for one direction of rotation only, and some care must be taken when applying the test herein described to machines equipped with them.

The question may be raised as to what effect this method of testing will have on the water-wheels; whether impelling them directly against the flow of water will not result in strains and distortions that may be injurious. The writer has referred this subject to a number of the most prominent water-wheel builders in the United States, and very few have cared to make any very definite statements on this point. The consensus of opinion, however, seems to be that there is little question of harmful stresses in high-head wheels, but there may be some doubt as to low-head units. The writer would recommend conferring with the water-wheel builders in each individual case where this method of test is being considered. It is believed that when this method shall have become better known and more generally used, wheel builders will be less conservative about approving it.

THE HYDRAULIC RAM

IN response to an inquiry from one of our readers concerning the operation, etc., of the hydraulic ram, we have pleasure in reproducing an article covering same which appeared in our columns some years ago, believing that by doing so the information will be appreciated by others as well.

The principles underlying the construction and operation of the hydraulic ram were recognized as early as 1775 by John Whitehurst, who in that year communicated to the Royal Society a paper describing a machine of a similar type in which the overflow or waste valve was operated by hand. The next improvement was made by a Frenchman, Joseph Michael de Montgolfier. He was the first to see that the variable pressure, produced by changing the velocity of a column of water, could be utilized to operate the valve. Since that time, although numerous improvements have been made in the way of securing quick action of valves by aid of springs and weighted levers, the ram is essentially the same as in its earliest form.

A drive pipe A, Fig. 1, takes water from a source of supply H, to a chamber which contains the valve V. This valve, which opens inwardly, is called the waste or overflow valve. In another part of the same,, or communicating chamber, is a check valve V_2 which leads to the tank into which water is being forced and which has a water level considerably above that of the supply tank. When V_1 is opened, the column of water in the drive pipe is set in motion, and will finally attain a velocity which builds up a pressure under V_1 sufficient to close the waste valve. The energy of the moving mass in the drive pipe cannot immediately be dissipated, therefore, the pressure in the chamber rises and lifts the check valve, allowing some of the water to enter the air chamber W, compressing the air and forcing an equal amount of water into the tank C. When the water in the drive pipe comes to rest, V_2 closes, V_1 opens, and the cycle is repeated. The pressure may for an instant be slightly less than atmospheric, and advantage is taken of this to introduce a small amount of air through an air valve. This air replenishes any part of the supply in the air chamber which may be carried out with the water.

Although the ram may have a high efficiency, it is wasteful of water, and the form shown in section in Fig. 2 has been devised to pump pure water with a minimum of waste. Connection is made at A to the source of waste water, which may be any polluted water available. The connection to the potable water should preferably come from a source under slightly greater head than the impure water. In this ram the waste water consists mainly of that entering at A but, in part from that entering at I and, if the capacity of the space between the waste valve B and the check valve C is greater than the amount of water delivered per pulse, no impure water can enter the chamber D. In this ram the air valve is placed at E.

The hydraulic ram lends itself readily to variable demand, which can be met by either changing the weight of the waste valve or adjusting its stroke. Its greatest field is in the water supply for small towns where the cost of maintenance and attendance must be kept as low as possible.

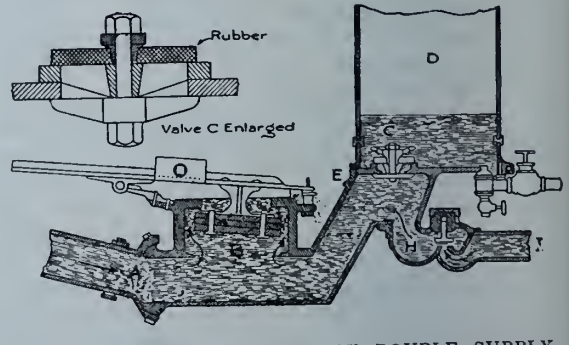

FIG. 2.—SECTION OF DOUBLE SUPPLY HYDRAULIC RAM.

C.A.S.E. Convention, Equipment and Supplies Exhibition

Arrangements are now well nigh complete for this annual enterprise, and judging by the efforts being put forth to secure a bumper attendance of operating engineers and power plant executives, the numerical response may easily surpass that of any previous gathering.

THE following provisional programe has been arranged for the annual convention of the Canadian Association of Stationary Engineers and Supplies Exhibition, to be held at Toronto from July 24 to 27 inclusive. Premises have been rented at 70 King Street West. The exhibitors will occupy the ground floor, while the first floor will be used for the convention sessions. It has been decided to keep the exhibition open each day, excluding Wednesday, July 25, which has been set apart for a trip to Niagara Falls, via Lake Ontario.

Tuesday, 24th

Convention opening by a member of the Board of Control. Smoker in the evening—boxing and music. Entertainments and outings for visiting ladies.

Wednesday, 25th

Boat leaves Yonge Street wharf at 9 a.m. for Lewiston, N.Y., where the trolley will be taken to Niagara Falls, N.Y., via the Gorge route. There the whole party will be entertained at luncheon by the National Association of Stationary Engineers. Before crossing to Niagara Falls, Ont., a visit will be paid to the Shredded Wheat factory. The return trip will take in the Canadian side of the Niagara River. Queenston Heights will be visited, following which, at 6 p.m., the boat leaves for Toronto, arriving there at 8.30 p.m.

Thursday, 26th

At 10 a.m., annual meeting of Exhibitors' Association. C. A. S. E. sessions. In the evening there will be an automobile trip round the city, and then to Scarboro Beach Park.

Friday, 27th

Closing day. No special feature arranged as yet.

The Exhibitors' Association executive this year is as follows:—Hon. President, H. P. Stevens; Past President, H. L. Peiler; President, Earl F. Hetherington; 1st Vice-President, Lloyd Archibald; 2nd Vice-President, C. N. Schragg; Treasurer, B. G. Newton; Secretary, Gordon Keith; Asst. Secretary, L. H. Rumage; Chairman Exhibit Committee, James E. Fiddes; Entertainment Committee, A. W. Crouch; Reception Committee, H. T. Ramshaw.

At one or other of the Grand Lodge sessions, the question of Graded Certificates for engineer operators in the Province of Ontario is likely to be fully discussed, and in view of the general unanimity existing as to the need that an enactment concerning them be placed on the Statute Book, a resolution will most likely be put and adopted for action by the Ontario Legislature.

Arrangements have been made for an open session, at which addresses will be given by Dr. Riddell, superintendent, Trades and Labor Branch, Province of Ontario, and by Louis Guyon and W. C. McGhie, chief examiners of License Board, Quebec and Ontario Provinces respectively; while papers will be read by D. M. Medcalf, chief of Boiler Inspection Department, Province of Ontario, on the History of Boilermaking in Canada, etc.; by W. G. Forbes, C.A.S.E. president, on Fans and Blowers, and by J. H. Hale, executive secretary, on the very important subject of Secretarial Efficiency.

LOOKS LIKE A BELT RECORD

AMONG the exhibits at the Centennial Exposition of 1876, says the "Compressed Air Magazine," was a 60-in. double leather belt, 187 ft. long, shown by J. B. Hoyt & Co., of New York. This was the widest and largest leather belt that had ever been made, and was intended for the Augustine mills of the Jessup & Moore Paper Co., of Wilmington, Del., to whom it was delivered early in 1877.

This belt transmitted 650 to 700 h.p., travelling over a 24-ft. diameter pulley on the engine to a 9½-ft. pulley on the line-shaft, at an engine speed of 52 r.p.m., or a belt speed of 3,920 ft. per minute, or 44.5 miles per hour. This mill operated continuously, starting at midnight Sunday and continuing in operation until midnight the following Saturday, so that the belt ran 24 hours per day, and averaged 300 days per year.

In 1902 the old belt had run 25 years, and in that time had travelled 8,010,000 miles, but its usefulness was by no means over. It always ran under damp conditions, because of its proximity to water, but notwithstanding these unfavorable conditions, when in 1908 it was sent to the factory to be cut into a 36-in. and other sizes. It was not rebuilt and there

1917 EXECUTIVE. C.A.S.E. EXHIBITORS' ASSOCIATION.

were no material repairs made upon it, and the same cement that was applied in 1876 is to-day holding the 36-in. belt together, and it has satisfactorily transmitted 350 h.p., equivalent to a working load of 198 lbs. per sq. in. of sectional area plus tension, from 1902. It is still running 144 hours per week, with prospect of several years more of usefulness in its present position. When the time comes for replacement, it will be possible to cut it up into smaller belts, which will probably be used successfully for many years in places where the performance is less exacting in its requirements, and these again, when their days of usefulness in the particular duty assigned them is over, may be cut into still smaller belts, and so on, and the final remains will have a value for heels and washers.

The longevity of this belt is not due to the lightness of its load, for its maximum transmission of 700 h.p. is equivalent to a working stress of 262 lbs. per sq. in., plus its tension—no small load; nor has it been due to superior care.

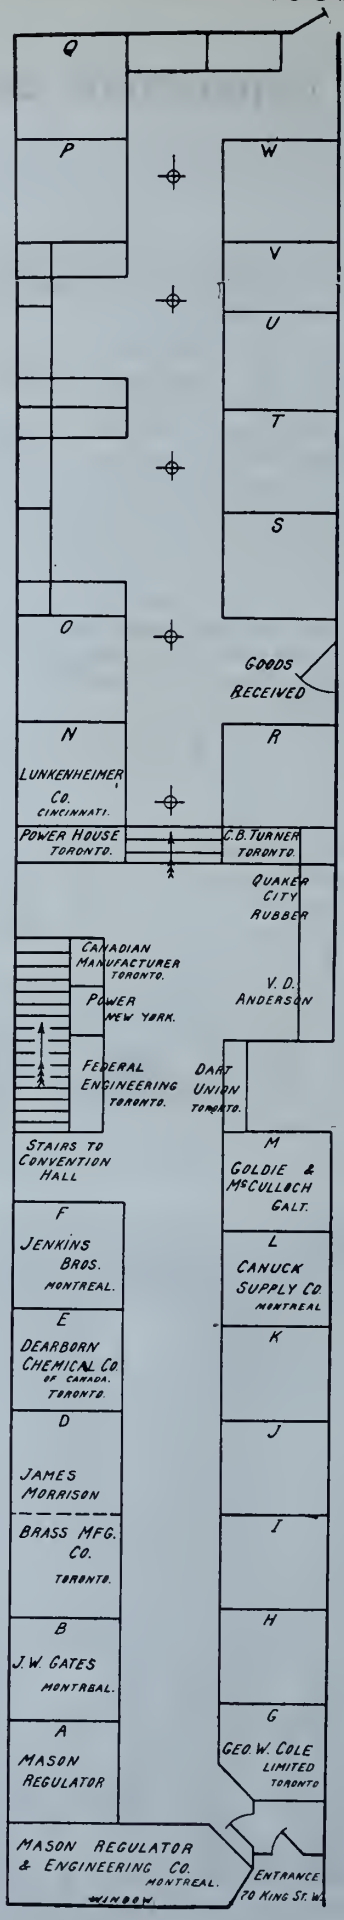
This belt, now operating over a 16-ft. engine pulley at 82 r.p.m. to a 6-ft. pulley on the main shaft, has a belt speed of 4,122 ft. per min., equivalent to 46.8 miles per hour, and in its present position in 15 years it has travelled 5,256,576 miles, which added to the distance which it travelled as a part of the 60-in. belt, equals a total of more than 13,266,576 miles with a probable considerable addition to be made to these figures by its subsequent performance.

The belt probably cost originally about $1,250. There has been expended upon it practically nothing for repairs, and the cost of transmitting 650 to 700 h.p. for 25 years, and 350 h.p. for 15 years, to say nothing of the transmission by the smaller belts cut from the original belt, has been $75 per annum for interest. The amortization of the original cost will be completed at an annual outlay of about $31, or a total cost of about $106 per annum; or disregarding the service rendered by the smaller belts, and averaging the loads with the years of service of the 60 and 36-in. belts at 570 h.p., this power has been transmitted at a cost of about 18c per horse-power per annum.

BOILER REPAIRS BY OXY-ACETYLENE

REPAIRS to boiler plates, which formerly were made by cutting a piece of the original plate out with cold chisel, and riveting a new piece on, are now being performed by Canadian firms with the oxy-acetylene process, the plates being cut with the oxy torch and the new pieces welded into place, doing away with riveting, which in many cases is largely impossible owing to lack of room. Oxy-acetylene welding for boiler repair jobs has been employed with complete success in the U.S., and has replaced the ordinary methods almost wholly in locomotive shops.

Copper Cliff, Ont.—The Canadian Copper Co. are building a pumping station for a sewage disposal plant.



LAYOUT OF C.A.S.E. EXHIBITORS' ASSOCIATION DISPLAY.

Screenings

Feared the Worst.—An Irishman coming out of ether in the ward after an operation exclaimed audibly: "Thank God! That is over!' "Don't be so sure," said the man in the next bed. "They left a sponge in me and had to cut me open again.' And the patient on the other side said: "Why, they had to open me, too, to find one of their instruments." Just then the surgeon who had operated on the Irishman stuck his head in the door and yelled: "Has anybody seen my hat?" Poor Patrick fainted.

* * *

Not Much to Ask.—The landlady bustled up to her new lodger as he came down to breakfast the first morning.

"Good morning, sir," she wheezed.

"Good morning," said the lodger.

"I hope you've had a good night's rest," said the landlady.

"No," said the mild-mannered little man. "Your cat kept me awake."

"Oh," said the landlady, tossing her head, "I suppose you're going to ask me to have the poor thing killed."

"No-no, not exactly," said the gentle lodger. "But would you very much mind having it tuned?"

* * *

Hoaxing a Bishop.—Funny stories are told about Archbishop Trench, who, seeing one day in Dublin a little girl trying to reach a door-knocker, came to her assistance.

"Rap hard!" said the little innocent. He did so.

"Now, run like the very devil!"

Trench always feared paralysis. One day at a dinner party he started probing his knee with his fork, and not feeling any pain, exclaimed: It's come at last, I am afraid."

"It's my knee," said the lady next to him!

* * *

The Scotch of It.—An enterprising drummer attempted to bribe an old Scotch merchant by offering him a box of cigars.

"Na, na," said the old chap, shaking his head gravely. "I canna take 'em."

"Nonsense," said the drummer. "If you have any conscientious scruples you may pay me a quarter for the box."

"Weel, weel," said the old Scot. "I'll tak' two boxes."

* * *

Hotel Advertising.—The customer at a London hotel gazed at his plate.

"Waiter," he called. "I should like to know the meaning of this. Yesterday I was served with a portion of pudding twice the size of this."

"Oh," said the waiter. Then, after a moment: "Did ye 'appen to be sittin' by the window, Sir?"

"Yes."

"Then that accounts for it," he said confidently. "We always give people by the windows large portions. It's a good advertisement."

Association and Personal

Horace N. Dorling has resigned from his position of inspector for the Imperial Munitions Board to join the sales staff of the Albany Pump Co., Toronto.

W. N. Campbell, who for 22 years was with the Reeves Pully Co., Toronto, has jointed the sales staff of H. W. Petrie, Ltd., Toronto, in the transmission department.

H. J. Matthews, general manager of the Quebec Street Railway, Heat & Power Co., died on July 3 at the Jeffery Hale Hospital, Quebec, from an operation.

George Beardmore, Toronto, and **W. G. Ross,** of Montreal, president of Asbestos Corporation of Canada, have been elected to the board of directors of the Canadian General Electric Co.

S. R. Parsons president of the British-American Oil Co., Toronto, was elected president of the Canadian Manufacturers Association at the annual meeting in Winnpeg last month.

W. R. Burge, who recently resigned as Toronto manager of the Jenckes Machine Co., is now a member of the Ontario sales organization of the Canadian Allis-Chalmers, Ltd., Toronto.

N. A. Marsh, of the John verMehr Engineering Co.'s engineering staff, Toronto, has left for an extended trip to Brazil, South America, to supervise the erection of the verMehr water filtration plant which is being constructed at Pernambuco.

Stationary Engineers Meet.—At the annual meeting of the Canadian Association of Stationary Engineers in the Temple Bldg., Toronto, the following officers were elected: President, H. Stevens; vice-president, S. Bamfrith; treasurer, John Brown; recording secretary, G. F. Moore; financial secretary, A. M. Wickens; conductor, H. Taylor; door keeper, W. Turner; delegates to the annual convention, J. Brown and S. Bamfrith; Alternatives, H. Stevens and T. Pope. The convention will be held in Toronto this month.

Lawford Grant has been appointed managing director and treasurer of the Eugene F. Phillips Electrical Works, Ltd., Montreal. Mr. Grant came to Canada in 1907 as president and managing director of the Canadian British Insulated Co., Ltd. In 1913 he accepted a position as assistant manager of the Phillips Co., and now succeeds **Geo. H. Olney,** who was head of that firm for eighteen years, Mr. Olney having recently retired owing to ill-health. Mr. Grant is a civil and electrical engineer, and was formerly engineer for the British Insulated and Helsby Cables, Ltd., of England.

Capt. T. E. Ryder, who has recently been promoted for distinguished conduct, is manager of the Canadian Fairbanks-Morse Co., St. John, N.B., on leave of absence for active service. Capt. Ryder has also been awarded the Military Cross, and on more than one occasion mentioned in despatches. He was, previous to the

CAPT. T. E. RYDER, M.C.

war, an officer in the St. John Battery. When war broke out he immediately enlisted for active service, and was attached to the Ammunition Column, Heavy Battery.

David Spiers one of the most prominent citizens of Galt, Ont., died there this month. He was 85 years of age, and had resided in Galt continuously since 1851, when he came to Canada from Scotland. He was at one time owner of the Galt Electric & Gas Light Co., until the advent of the Hydro system.

Brantford No. 4, C.A.S.E.—The members of this lodge met in their rooms, 17 George Street, on July 6. There was a good attendance, and what was perhaps of most importance, seventeen candidates were duly initiated. Election and installation of officers took place as follows:—Past president, John Lea; president, David L. Webster; vice-president, Joseph Ogle; recording secretary, Harry Doeringer; financial secretary, A. N. Matthews; treasurer, Fred. Owens; conductor, Thomas Hurst; doorkeeper, Wm. Powell. This lodge meets every Thursday evening throughout the year.

Kitchener, No. 9, C.A.S.E.—On June 24, the members of this Lodge, headed by Executive Vice-President, R. F. Goftn, Julius Luft, and Lodge Secretary, Conrad Ott, motored to Hamilton where they were met by Executive Secretary J. H. Hale who chaperoned them on a tour of the numerous places of interest to be found in the "Ambitious City." The Kitchener Lodge has been entrusted with the complete revision of the Ritual, Constitution, and By-laws of the Canadian Association of Stationary Engineers, and advantage was taken of the occasion to discuss questions relative to the revision that will be dealt with finally at the coming Convention. Not the least important of these are the issuance of Grade Certificates by the Association to its members, and the operation of its recent Federally enacted Bill of Incorporation.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President.—Robert Dyson, Guelph, Ont.
President.—W. G. Forbes, Montreal, Que.
Vice-President.—Rodger F. Gofton, Kitchener, Ont.
Treasurer.—A. W. Heath, Hamilton, Ont.
Conductor.—William Cooke, Belleville, Ont.
Doorkeeper.—John W. Beasley, Chatham, Ont.
Secretary.—John H. Hale, Hamilton, Ont.

Boiler Setting Relative to Fire-Grate.—Considerable interest has been aroused among engineers as the result of experiment concerning and investigation into the setting of steam boilers relative to their firegrate. It has, I understand been conclusively proved that the hitherto accepted practice of having the heating surface most directly in contact with the heat of combustion from the fuel bed just as close down to the latter as possible, is much less efficient from a steam generating point of view than when the distance is twice or thrice that amount. It is just possible some of your readers have already had experience with boiler installations which exemplify the new type of setting—water-tube or return tube and, if so, it seems to the writer that no more opportune topic could meantime be profitably discussed in your columns editorially.—K.P.

FIFTY YEARS OF CONFEDERATION

ON the first of the present month, the completion of fifty years of Confederation of the individual Provinces of this Dominion was consummated and, needless to say, the day was marked by celebration becoming the occasion. That we have progressed during the elapsed period, and are still doing so, is readily apparent, although when we look back—far or not so very far, is it surprising that we have reached our present status? When account is taken of the grit and dogged perseverance of the men from the Motherland who in the early days "blazed the trail," and with their immediate successors in many instances, made roads, built bridges, harnessed waterpowers, dug canals, pinned ribbons of steel to the soil and stretched it across a whole continent, initiated agricultural and mineral development, established manufacturing, built ships and sailed them on our lakes, rivers and ocean coasts, we in these later years must perforce admit that ours is a goodly heritage, not only to be cherished and retained intact, but to be developed in manner worthy of those from whom it has been received.

In the half century that has elapsed, much to be nationally proud of has been accomplished and, as might be expected, there has been and still is in evidence, much to the contrary. We are at war, and have been so for nigh three long years, and just what the new half century on which we are about to enter has in store is largely matter of conjecture. At war, yes, and in diverse ways we have been made to realize it. We are prosperous, yes, but there is an uncanniness about it that bids us take heed. We are progressing, but is the overwhelming tendency in the right direction? We are confident to the point of self-sufficiency, but is it all justifiable? While we have played a part, and a most worthy one up to the present, comparatively our vision, and consequently our activities, have been "cramped, cabined and confined." In a word, we have been poor "mixers." A new era in every phase of our national life has already been ushered in as a result of this world-war and, as a consequence, the trend of our past half century of progress is likely to evidence many offshoots if we would not only maintain our present position, but occupy those others that meantime are offering, and the possession of which will unfold a myriad others.

The omens are in every respect favorable to not only an unbroken continuance of the progress record of advancement of the past fifty years, but to its being stimulated in every sphere of our national life. Whether, in this war-time, we have done all we might or should have done, may be perhaps a moot point, everything considered. We have, however, not done badly, pharisaical even though the statement may seem; but much more is required and, needless to say, it is going to be forthcoming. We have a world-duty to perform, in the doing of which, our native or adopted country, as the case may be, will, as sure as night follows day, be a beneficiary. These are days when liberty—individual and national alike, is being strenuously assailed by tyranny of the foulest dye on the part of a sister nation, and to ensure that the part we have already played in the discomfiture of her tyranny may end in nothing short of her being completely squelched, if for no other reason, although there are others equally good, let the last fit man and the last, however hard-earned dollar, be spent.

CANADIANS should not consider that 1917 will be the only year that rigid economies must be practised. There is no knowing at this date when the war will end, and even after it has ended there will be urgent need for Canada's surplus of food for many months while Europe is being regenerated.

The Operators' Point of View

OVERCOMING TROUBLE WITH STEAM PIPE

By H. Westwood.

IN your May issue J. James made reply to my letter regarding a change he made in steam pipe to his engines. If I understand the section of this journal known as "Operators' Viewpoint," correctly, it is for power plant operators to express their views and for criticisms to be made there, on and not for the purpose of advertising who we are and what we have been. In the first part of his reply he states, "No doubt I am right regarding certain conditions." Just so, the circumstances I referred to did the trick.

We have a Gebhart steam flow meter that speaks the truth on the flow of steam, air, and gas, and it is not theory but a practical instrument found in most up-to-date power plants, that have not gotten rusty lying in the locker. I have a copy of the letter I sent to the April issue, and it did not state that the receiver was 8 ft. in diameter.

Mr. James could not have analyzed my figures with regard to the amount of steam the receiver would contain, or he would have found thereby that the receiver was 8 ft. long and 24 in. wide. I did not deny that his making this change did not remedy the trouble. What I did say, and still adhere to, is that no more steam flows through the 5 in. pipe since the change was made than there did before. With regards to the balance of his reply, which deals mainly with the equipment of his plant, I might say, if we compare the piping in his plant from a financial or first cost standpoint, I am afraid the latter are buying gold mines in their pipe lines.

HANDY SPRING SAFETY VALVE CHART

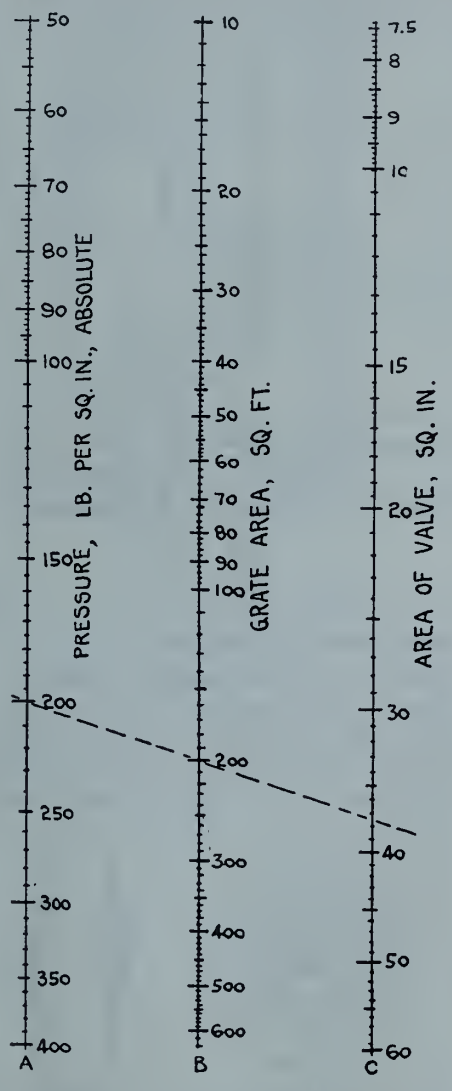
By N. G. Near.

THIS straight line computing chart is based upon the well-known British Board of Trade formula for spring safety valves:

$$A = \frac{37.5\,G}{p}$$

where A=area of valve in sq. in.;
where G=grate area in sq. ft.;
where p=steam pressure in lb. per sq. in. absolute.

As is well known by most marine and locomotive engineers, lever safety valves are impractical on locomotives or on shipboard because of the vibrating or oscillating movement, and for that reason spring loaded valves are used entirely. In marine service two duplicate valves are required by the Board of Trade. The diameter of the valve, also,



HANDY SPRING SAFETY VALVE CHART.

must be 2 inches or more, while the maximum lift of the valve must be at least one-fourth of the diameter. Well, this chart is based on the formula given above. To use the chart simply lay a straight edge across once as indicated by the dotted line and the answer is immediately found in column C.

For example—If the grate area is 200 sq. ft. and the steam pressure is 200 lb. per sq. in. absolute, what must be the area of the valve?

Connect the 200 (column A) with the 200 (column B) and the extension of the line through column C shows the answer to be 37.5 sq. inches. The dotted line drawn across this chart shows how the problem is solved.

Again, the chart may be used "backwards" very nicely for determining grate area or pressure when the valve area is known. Simply swing the straight edge around the area as a pivot and the intersections with columns A and B give the corresponding pressure and grate area for any pivotal position.

The range of the chart, I believe, is wide enough to cover the needs of nearly every marine or locomotive engineer. It includes all pressures from 50 to 400 lbs. per sq. in. and grate areas from 10 to 600 sq. ft.

WHY THE RADIATORS WOULD NOT HEAT

By James Creery.

WHEN the writer took over his present position in a local sanitarium he found that among other things, two radiators on the top floor of one building would not heat. The heating equipment operated on the vacuum system, the vacuum trap operating satisfactorily with a good vacuum. As it was spring time and my time was fully occupied in getting things generally into shape, etc., I put off trying to fix this particular trouble until the summer months and forgot all about it.

When starting up the heat for the following winter, however, I was forcibly reminded of the trouble by the occupants of the room. A good vacuum could be obtained on the return side, so I bypassed the reducing valve and raised the pressure up to about 20 lbs., which heated these two radiators all right, although all the other radiators were hot enough on 1½ lbs. After they were heated I would reduce the pressure again. but was soon called on for more heat. so determined to trace the pipes and found that the troublesome radiators were entirely independent from all the others on that floor. The steam and return lines ran clear through from the basement to the top floor without any branches from either of them.

No provision was made for handling the condensation in the steam pipe which accordingly filled up so that when the weight of water equalled the pressure of the steam no heat could get into the radiators. By inserting a Webster vacuum

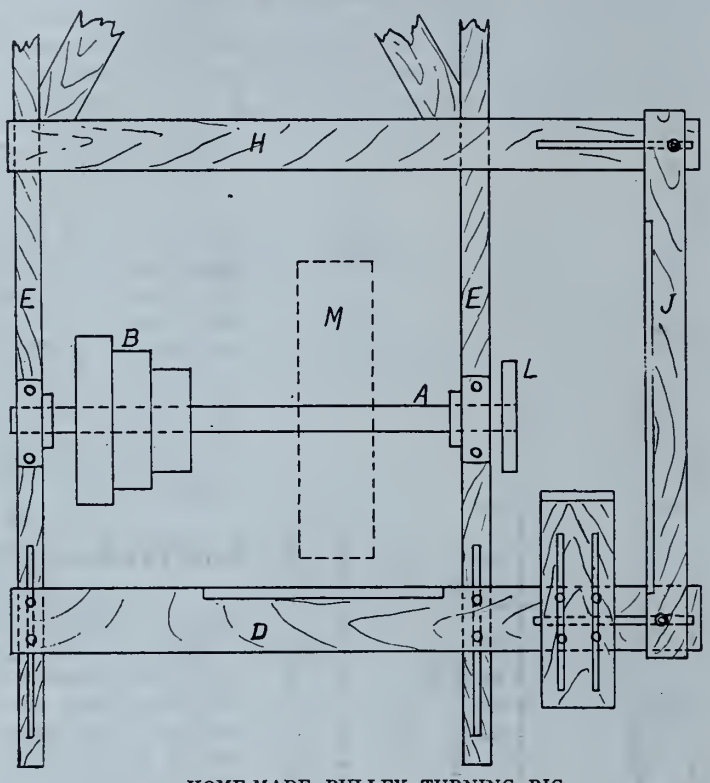
trap at the lowest point of the steam line and joining it to the return line the trouble was overcome, and the two radiators are now heated satisfactorily on 1½ lbs. of steam the same as the others. Moral: There is always a reason for everything.

PULLEY TURNING RIG

By J. E. McCormack.

THE accompanying sketch shows the plan of a rig which I fixed up and used for turning pulleys. The size and proportion of the parts should be governed by the class of work to be done. I use this one for pulleys up to 28 in. dia., with bores of 1½ to 3 in., and used 2 x 4 in. scantling for the pieces EE, and 1 x 4 in. for legs and braces, these parts being made of wood. The arbor used was 1 7/16 in. dia. and 3½ feet long, and is driven by the cone pulley B.

The dotted lines at MM indicate the position of a pulley to be turned. L is a disc or face plate. D and H are supported by the side pieces and in turn support the chisel rests C, K, J. These are adjustable and removable in much the same manner as the long and short rests in wood turning lathes. D is movable to and from the arbor to accommodate different sized pulleys.



HOME-MADE PULLEY TURNING RIG.

The arbor is held from end motion by a collar just inside the frame and against the bearings. One could be put on each side of one bearing if preferred. The bearings are raised so that the center of the arbor is four inches above the upper surface of the pieces EE, thus allowing room for D C J K without raising them too high for convenience. A supply of bushings is kept for use in fitting pulleys of different bores to the 1 7/16 in. arbor.

Very small pulleys are turned on the face plate, being held by a pair of wood screws passing through the disc. The end of the arbor can be fitted with pin or screw as desired, but I did not do so, and, perhaps because of this, I found that in making small pulleys it was better for one not to bore them until after they were turned. After finishing, I make a few circles on the side by using a pointed chisel on the rest J and these serve as a guide for centering exactly when setting up the work, and any slight shifting of the work previous to the lighter finishing cuts does not throw the finished pulley out of true when hung.

FIXING A BALKY VALVE

By J. Haliburton

SOME time ago I was asked to fix a balky hand force pump of the type in which valves are made as in Fig. 1, the same piece of leather serving both as gasket and as valve flap. On one side of the flap there was a brass plate covering most of the said flap and held in place by a screw passing through the leather and screwing into the plate. The head of this screw was broad, yet thin, and was slotted for a screwdriver. Of the three of these valves in the pump not one of them seated properly, because the leather had acquired a "set" in a shape that kept the flap sticking up, as shown in Fig. 2.

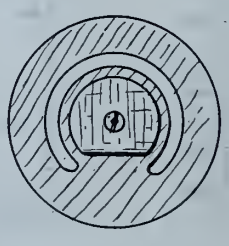


FIG. 1.

FIG. 2.

OVERCOMING TROUBLE WITH HAND FORCE PUMP VALVE.

By removing the leathers from the pump, taking the screw out, and putting the plate and screw each on the opposite side of the leather from what they had been before, and then putting the leathers back into the pump other side up from what they formerly were, I secured the aid of this "set" in the leather to help hold the valve to its seat. After treating each valve in this manner, and priming the pump, it held water O.K., and worked satisfactorily right along although the less drastic remedies previously applied had proved unsuccessful.

REMOVING BROKEN SET SCREWS

By D. A. Hampson

THE quickest removal of a broken set screw ever witnessed by the writer was accomplished by a special tool made from an overgrown three-cornered file. About two-fifths the length of the body of the file had been broken off its smaller end, and the newly broken end on the larger piece ground down to a pyramid shape. Most of the tang was also removed. This tool had been made some time before and for this class of work. The other tools used were, a drill, a lever, and a wrench. The diameter of the drill used was possibly half, but not more than that, of the screw to be removed.

A hole was first drilled in the centre of the broken screw, deep enough to give the special tool a chance to work without its point coming in contact with the bottom of the said hole. This special tool was then placed with its sharp end in the hole and the lever placed inside the frame of the machine and across the tang of the tool, then pressure applied to force the tool into the hole. The tool was then turned backwards with a wrench. At first it acted like a countersinking tool, but soon got hold of enough metal to enable it to give the broken screw a turn and the job was soon finished.

On paper the job looks bigger than it really is. A large three-cornered or square can be easily made into one of these tools and if a size strong enough for the work, will last indefinitely. The drill, wrench and lever are invariably on hand in any plant. The depth of the hole required is very much less than where a square tool with parallel edges is used for turning the screw.

These columns have already given us some kinks on which a screw clamp is useful and I believe that in connection with the above scheme a screw clamp could be used sometimes more conveniently than, and instead of, the lever. It would be advisable to select one having a depression in one of its bearing surfaces into which the tang of the tool could bear while in use. With both clamp and lever to hand, the one best adapted to the construction of the affected part and the neighboring members could be used.

LAST RESORT ON A BALKY LUBRICATOR

By J. E. McCormack.

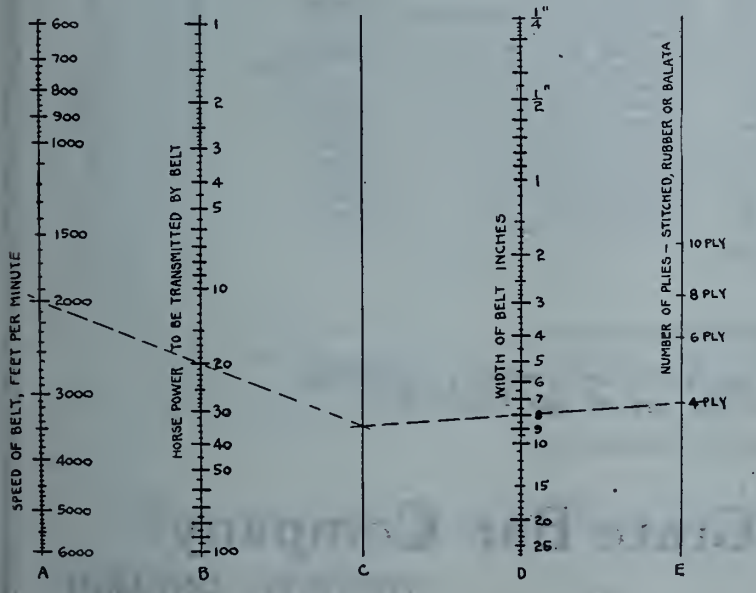
ONE of a pair of engines of which I was once in charge was equipped with a type of single connection lubricator in which the rate of feed was observed by watching the drops of water pass down between a glass disc and a polished brass plate behind it. This lubricator generally gave excellent service, but one day it

was not working so well as usual and the former engineer, now promoted to superintendent, happened along just as I was tinkering with it. When he saw that my efforts had failed, he remarked, "Perhaps it is airbound," and applied a bicycle wrench to the nut connecting the brass arch to the top of the condensing chamber, turned the nut a little to allow leakage, held it there until steam began to come, tightened it again, took a look at the sight feed, and passed on. The lubricator was working nicely. During my stay this lubricator did not balk many times and when it did I always tried the orthodox remedies first. If they did not succeed I then tried this remedy always as a last resort, and so far as I can recollect, it always succeeded probably partly because by the time I got around to the kink no trouble except the air-bind remained. I can not explain the why and wherefore; I only know it produced results. I am inclined to think this trait is peculiar to that particular class of lubricator if not to that individual lubricator itself, but as I consider the remedy simple and not generally known, I pass it on, thinking it may some day help out some one else using a lubricator of similar construction.

HANDY CHART FOR SOLVING FABRIC BELTS IN PLIES

By N. G. Near.

INASMUCH as charts are rare on the subject of power transmitted by fabric belts, the writer has taken it upon himself to produce something that doesn't mention the word "leather" at all. Usually we are told that a 4-ply stitched canvas belt is equivalent to a single leather belt and then we are supposed to know the rest, but we usually have to hunt around in our handbooks for formulae on leather belts, the whole thing is thus highly unsatisfactory. With this chart you simply lay a straight-edge across twice, and the answer is found without difficulty. Knowing any three of the functions—speed, power, width and ply, we can easily determine the missing one.



HORSE-POWER—WIDTH CH ART FOR FABRIC BELTS.

For example, what width of 4-ply Balata belt running at a speed of 2,000 feet per minute is necessary to transmit 20 horsepower?

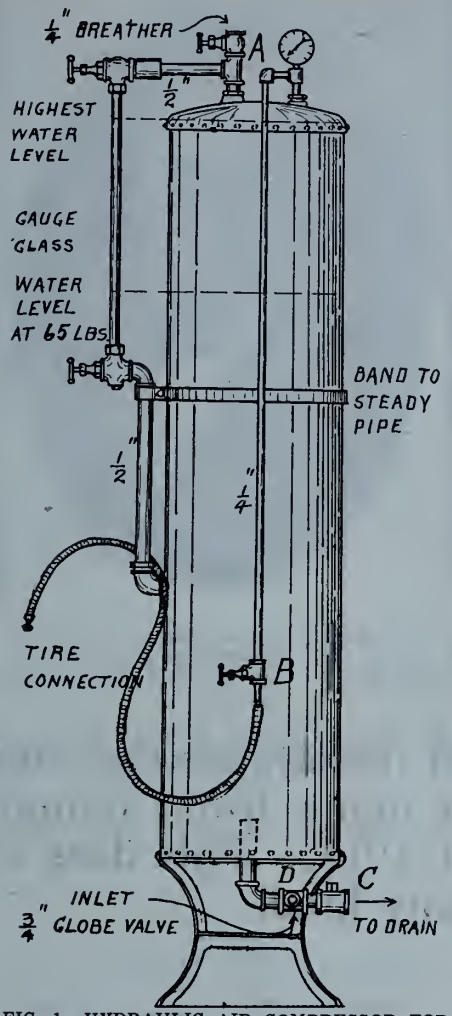


FIG. 1. HYDRAULIC AIR COMPRESSOR FOR TIRE SERVICE, ETC.

Connect the 2,000 (column A) with the 20 (column B), and locate the intersection with column C, then from that point of intersection run over to the 4-ply mark (column E), and the intersection with column D will give the answer as 8 inches.

Again, if we had known the width and wanted to determine the ply, the method would have been about the same. It is so simple that I am sure any reader will understand by merely inspecting the chart.

This chart is applicable to the well known belts made up in plies such as stitched canvas, rubber, and Balata, and the range, it will be noted, is wide enough to care for any ordinary condition.

HYDRAULIC AIR COMPRESSOR FOR TIRE SERVICE, ETC.

By C. Mills

THE accompanying sketches illustrate a simple device to inflate automobile or bicycle tires without the usual manual labor. It is cheaply constructed and very serviceable. The tank is an ordinary 30 gal. water service tank using water at city pressure—60 to 70 lbs.—to displace the air, which is taken away by a small pipe at the top and connected to the tire by a small hose. The tank illustrated in Fig. 1 has been found large enough for tires up to 32 x 3½ in., one filling of water being sufficient for two completely deflated tires or four semi-deflated.

To inflate tire, connect hose coupling to valve stem, close the valves A and C, and open D. The air pressure will rise till it is equal to the water pressure.

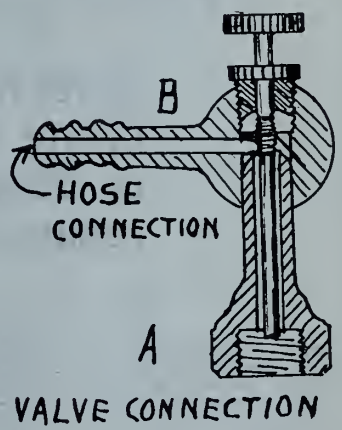

FIG. 2. HYDRAULIC AIR COMPRESSOR FOR TIRE SERVICE, ETC.

When the necessary pressure is acquired, close valve D. Air can be used until the water in gauge glass shows at high level marks, which is about 1 or 1½ in. from top head of tank. Beyond this level, water is liable to get into the air pipe and into the tire. To drain tank, open valves A and C. When empty, it is ready for another charge.

The pressure in the tire will be somewhat less than that in the tank, caused by the tension of the small valve spring in valve stem of tire. If full tank pressure is required, it is necessary to use a small fitting like Fig. 2, which is easily made. It is composed of the usual coupling A soldered into a brass fitting B. A small threaded stem passing down through a stuffing box engages the valve stem, forcing it down from its seat. When inflating tire, turn the small screw two or three turns down after the coupling is connected on valve stem, when tire is full, loosen back the screw before taking off the coupling.

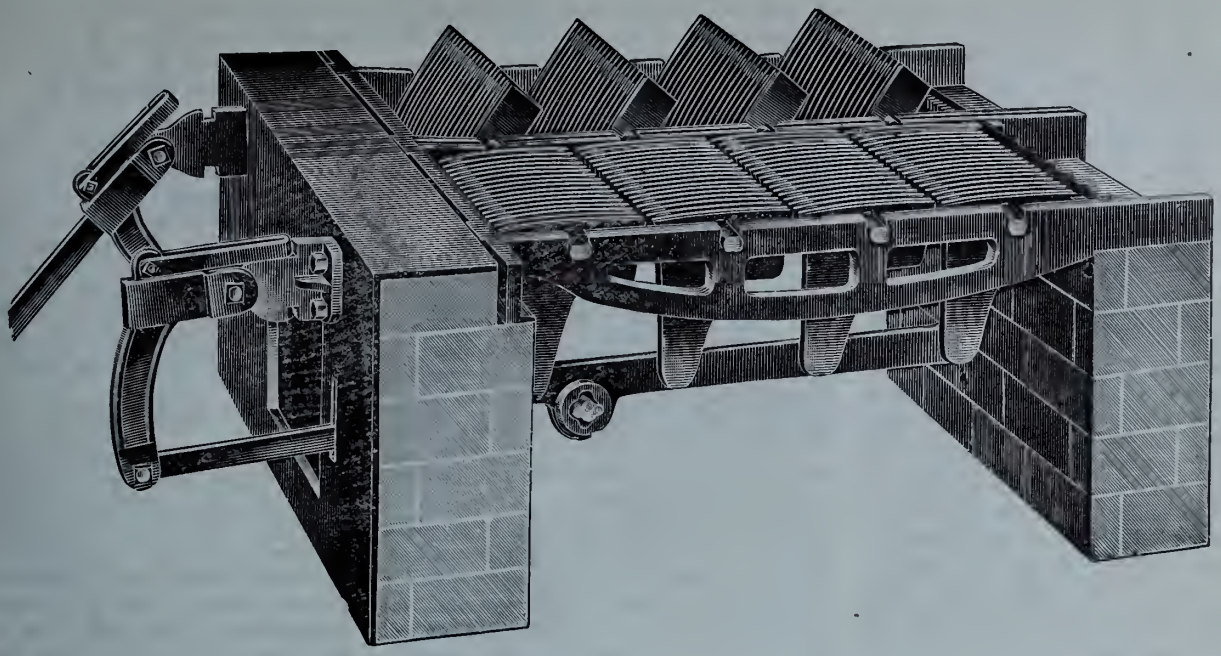
Boiler Repair & Grate Bar Company

84 CHURCH STREET -:- -:- TORONTO, ONTARIO



The 20th Century Shaking and Dumping Grate Bar

CHAMPION OF ITS CLASS

WE make the following proposition to all reliable firms in order that you may be convinced of the economical value of our grates:

We will install one set of our Grate Bars of any size, under any kind of a boiler for a trial period of thirty days, and guarantee to make a saving of at least 10% in fuel, and further guarantee the grates to give entire satisfaction in every particular. We leave you to be the judge. If grates are not entirely satisfactory we will remove them and place yours as we found them, without any expense to you whatever.

The best of Steam Specialties of every description carried by us.

Write us about any change you might be thinking about making in your boiler room. We will advise you FREE OF CHARGE.

A SPECIFIC INSTANCE OF SPECIFIC GRAVITY

By J. E. McCormack.

WHEN the writer tells anyone that he has seen solid pieces of iron actually floating on liquid—yes, solid pieces of iron actually floating on liquid" — he takes grave risks of having his word doubted, but the story is really true. Not expecting to see such a thing at the time, he poked with a stick to make sure if what he saw was foreign matter, and floating. He then removed one of the pieces to ascertain its nature, and, upon finding it to be iron, put it back into to liquid again to make sure if it did float, and float it certainly did. A little common sense readily explains the phenomenon, but occasionally a fellow may not happen to be thinking of common sense when first looking at exceptionally uncommon occurrences. We are so accustomed to seeing iron sink that we do not expect solid pieces of it to float of their own accord under any circumstances and this fact might lead some one to sometimes quite innocently make the same experiment that procured for the writer the privilege of seeing iron floating.

The paper frictions of a certain machine needed re-filling and for this purpose were sent to a machine shop in another town. When they were returned one of them was too large to allow its shaft to go down into the bearings properly. Its neighboring friction wheel worked below it and therefore the remedy adopted was to re-babbitt the bearings, but with the shaft lined up an inch or more higher than before, the caps of the bearings being shimmed, or packed up accordingly. As this left a large space to be filled a couple of pieces of old sleigh-shoeing were put in the bottom of each box to help fill up the space and thus save babbitt. The scheme happened to work all right. Probably some of the blocking that supported the shaft was resting on these irons instead of the shaft having been supported by independent blocking placed outside of the bearings.

Some year later, when the frictions had become worn down considerably, the writer undertook to re-babbitt those same bearings, putting the shaft down to near its proper place again. The old babbitt was dug out and melted again for re-use (the shaft being one that ran at only a moderate speed), and as the specific gravity of the babbit was greater than that of iron those long forgotten pieces of old shoeing floated. I wonder by just how much (or little) one or more of them escaped rising up against the shaft while the melted babbitt was flowing around them. If anyone doubt the possibility he is at liberty to drop some spikes or some chunks of iron into a ladle of melted lead or babbitt some time and see for himself if the iron comes to the top or not.

The moral intended is: If anyone has an exceptionally large space to fill with babbitt, don't attempt to fill part of it with old iron without making sure to block it well away from the shaft itself for keeps, whether above or below, lest he afterwards finds that in places he has an iron to iron contact in his newly poured bearing.

Had it not been for the above experience, he would probably even yet have expected that iron placed in the bottom of a space about to be filled with babbitt would remain there even if depending only on its own weight to hold it down. He would probably not have mentally compared the specific gravity of the two metals.

PACKING POINTERS

A BABBITT METAL or brass ring in the bottom of the box of an outside packed plunger is a great aid to packing. It will pay for itself many times over, not only in cost of packing, but also in the general neatness and cleanliness around the pump.

When using packing with high pressure or superheated steam, it is not advisable to use cylinder oil as a regular lubricant. A mixture of cylinder oil and graphite is good, the cylinder oil simply serving to help flow the graphite into position. The graphite gradually fills in the smaller pores of the rod and levels them up, making a smooth surface. The smoother the surface, the less friction there will be between the rod and the packing.

Some engineers make a quick and permanent joint out of a self-vulcanized packing by turning on three or four pounds of steam after the joint is made, and when the joint is thoroughly warmed, dashing a few buckets of water over it, thus cooling the flange and the packing. This causes the packing to harden into position at once. It is a quicker process than that of self-cooling.

Packing if treated right will do a great deal of good honest labor for its master but, if forced, it balks and will not work. A man should be patient with packing, and use it very carefully until it thoroughly conforms to the shape of the box. If it be given plenty of room and well lubricated, it will last for years; but if squeezed into a confined space and run dry, it will soon lose its life.

Stuffing Box Notes

It is a good plan for every engineer to keep a little note book in which to tabulate the diameter or every rod, the diameter and depth of its stuffing box, and the size of the packing required. This enables an order to be made out quickly, and an the same time with certainty. The measurement of a rod in motion, is always guess work. It is also a good plan to number each box that requires packing, and keep extra packings on shelves in the order of the number, so that it can be quickly found in case of emergency.

A good engineer can pack with almost anything. A poor engineer can spoil the best of packing. An engineer, who treats carefully the packing which he puts in and takes care of it as he would a new suit of clothes, will find that it will stand by him and give good service. If he abuse it, however, particularly with the unwise use of a wrench, he will find that it will wear out very quickly. Patience and carefulness are the watchword of success with packing.

Before inserting a packing ring, it should always be dipped in cylinder oil. The advantage thus obtained, far more than compensates for the corrosive effect of the oil. The oil as a lubricant, prevents excessive friction and allows the packing to place itself in position without being burned, and while the oil will affect the rubber, it will not produce as quick and disastrous an effect as the excessive heat would, if no lubricant were used.

Sheet Packing

Some engineers make a practice of placing sheet packing in position on a flange and then cutting the edges with a hammer. This is very poor practice, as it leaves a bruised and ragged edge on the rubber which has a tendency to tear. The best way of cutting is to first mark the outline of the gasket on the sheet and then to cut with a sharp knife. This leaves a clean cut edge and lessens the danger of a blow-out.

When drawing up a gasket, draw the bolts up gradually and on all sides, so that the two flanges approach each other as nearly parallel as possible. If a gasket is drawn up tighter on one side at the start, the gasket is distorted and a probability of blowing out is almost assured. If there are eight bolts in the flange, draw number 1 partly, then skip to number 5, then to number 7, then to number 3, and then to the intermediate bolts. Repeat the same process, drawing them a little tighter. Repeat again setting them up in position.

Starting Up Economisers.—It has recently been pointed out that accidents occasionally occur during the operation of starting up an economiser early in the morning. A careless attendant, for instance on starting will sometimes open to the full the dampers in the economiser chamber, and so allow the whole of the hot flue gas to pass through the chamber, forgetting for the moment that the engines or turbines and the feed pumps have not yet been started up and that there is consequently no water flowing through the economiser. Under these circumstances, the enclosed water becomes heated, until eventually evaporation into steam commences. The level of the water in the vertical pipes then becomes gradually lowered, with the result that the upper portion of the pipes, being bared of water, suffer from more or less overheating. Further, the steam so formed, by coming into contact with the water on the boiler side of the outlet valve, when the latter is opened, tends to cause "water hammer" action. This causes crackling in the pipes, and has in some instances led to fracture and explosion and serious injury to the engineer-in-charge.

Operators' Instruction Course

EDUCATION PAPER—I.

IF THE temperature of steam at 5 lbs. pressure is 227.964 degs. Fahr. and 337.874 degs. at 100 lbs. pressure, how many degrees higher is the steam at the latter pressure?

Subtract temperature at 5 lbs. pressure from that at 100 lbs. pressure; thus, 337.874—227.964=109.910 degrees Fahrenheit.

* * *

The outside diameter of 2½ inch wrot iron pipe is 2.87 inches, and the inside diameter is 2.46 inches; how thick is the pipe metal?

Subtract the inside diameter from the outside diameter and divide your answer by 2; thus, 2.87—2.46÷2=.205 in. metal thickness.

* * *

In a cistern that will hold 326.5 bbls. of water, there are known to be 178.625 bbls.; how many bbls, does it lack of being full?

Subtract the number of bbls. of water known to be in the cistern from the whole content of the latter in bbls.; thus, 326.5—178.625=147.875 bbls. lacking.

* * *

A wrought iron rod is 2.53 inches in diameter; what must be the thickness of metal turned off so that the rod will be 2.495 inches in diameter?

Subtract the rod diameter after turning from its original diameter and divide your answer by 2, thus, 2.53—2.495÷2 = .0175 in. of metal to be turned off.

* * *

The stroke of an engine was found by measurement to be 2.987 feet. How many feet will the cross-head pass over in 600 revolutions?

There are two strokes in each revolution, therefore the stroke in feet multiplied by 2 and by the number of revolutions will give the total crosshead travel in feet; thus, 2.987× 2 ×600=3584.4 feet.

* * *

If a steam pump delivers 2.39 gallons of water per stroke, and makes 51 strokes per minute, how many gallons of water would it pump in 58½ minutes?

Multiply the gallons pumped per stroke by the strokes per minute and by the number of minutes; thus 2.39 × 51 × 58.5 = 7130.565 gallons.

* * *

In a steam engine test of an hour's duration the horse power delivered was found to be as follows, at 10 minute intervals:—25.73, 25.64, 26.13, 24.20, 26.7, 26.34; what was the average horse power?

Add together the horse powers registered at the various intervals, and divide the total by the number of intervals which in this case is six; thus, (25.73 + 25.64 + 26.13 +24.20+26.7 + 26.34)÷ 6 = 25.79 average horse power per hour.

* * *

There are 31.5 gallons of oil in a barrel, how many barrels will there be in 2787.75 gallons.

Divide the total gallons by the number of gallons in one barrel; thus, 2787.75 ÷ 31.5=88.5 barrels.

* * *

A car load of coal, weighing 18.75 tons, costs $60.75, how much is it worth per ton?

Divide the total cost by the total tonnage, thus, 60.75 ÷ 18.75 = $3.24 per ton.

* * *

A keg of 3/16 in. by 1⅝ in. boiler rivets weighs 100 lbs., and contains 595 rivets; what is the weight of one rivet?

Divide the total weight of rivets in the keg by the total number of rivets, thus, 100 ÷ 595 = .168 lbs. weight of each rivet.

* * *

The stroke of an engine is 14 inches; What is the length of the crank in feet, measured from the center of shaft to center of crank-pin?

The distance between shaft and crank pin centres or crank throw is equal to half the engine stroke, therefore, the amount will be 7 inches; but as the answer is required in feet it becomes necessary to divide the crank throw in inches by 12, thus (14 ÷ 2) ÷ 12 = .5833 feet.

* * *

A steam pipe fitted with an expansion joint was found to stretch 1.668 inches when steam was turned into it; state the expansion in decimal parts of a foot?

The answer to this question is found by simply dividing the inches of expansion by 12, there being twelve inches in one foot; thus 1.668 ÷ 12 = .139 feet.

READERS' QUERIES AND ANSWERS

Question.—Give principal dimensions of a 60 inch diameter by 20 ft. long horizontal return tubular boiler?—A.S.

Answer.—In the first place it should be pointed out that horizontal return tubular boilers of 60 inches diameter are never made 20 ft. long. The standard lengths are from 12 ft. to 18 ft. long. The shell thickness varies from 5/16 in. to ½in., depending on the working pressure; the heads are ½ in. thick; the tube diameters may be 3½ ins. or 4 ins., and are in number 71 and 54 for the respective diameters. Basing the heating surface on 12 sq. ft. per horse power, the range is from 900 and 800 sq. ft. for a 60 in. diameter by 12 ft. long boiler, with 3½ in. and 4 in. diameter tubes respectively to 1700 sq. ft. and 1500 sq. ft. for a 60 in. diameter by 18 ft. long boiler for 3½ in. and 4 in. tubes respectively. The horse power range is from 60 to 110 for the various boiler lengths. When manholes are fitted in either or both heads, the number of tubes is reduced, and therefore the heating surface.

* * *

Question.—The plant of which the writer is in charge has at the present time 4 return tubular boilers, each 48 in. x 12 ft., with 52 tubes, 3 in. dia. These boilers are served by a chimney 36 in. dia. x 60 ft. high, induced draft by fan being used. Power requirements demand an additional boiler 60 in. x 16 ft., with probably turbine or motor-driven forced draft fan. The present stack seems to me to be too small to take care of all these units when they are working together in the winter months, but it is desired to avoid the addition of another stack. Do you think that with good forced draft on the new boiler satisfactory service can be had. Souris lignite screenings are used, having a heat value of about 5,500 B.T.U.—the boiler pressure is 100 lbs. The connection from the new boiler would go direct to the chimney and not into the present smoke breeching.—J. R. S.

Answer.—Reliable authorities give the horse-power of a 48 in. x 12 ft. boiler at 50, so that your present chimney is taking care of at least 200 horse-power. The ordinary capacity of a chimney 36 in. dia. x 60 ft. high, is 141 horse-power, with a natural draft, but with induced draft such as you have, 200 horse-power is perfectly feasible. A boiler 60 in. x 16 ft. would rate at 90 to 100 horse-power, so that if the new boiler is to be run at full load right away, the chimney would have an overload of 50 per cent. As far as economy of operation is concerned, the provision of a new stack would be desirable, but if an overload on the induced draft fan can be taken care of, the present stack may quite well do for the present. It would be worth while connecting it to the present stack for a start, as the cost would not be great, and an additional stack could always be installed while it was under operation.

Question.—A gusset stay supporting a surface 13 in. by 13 in. is 10 in. deep by ½ in. thick; the fastening being by means of four ¾ in. bolts; what working pressure is allowable?—A. S.

Answer.—It is clearly evident that the fastening is the weakest feature of the stay; therefore, the combined area of the bolts under the thread must be used in the calculation for working pressure. Assuming the bolt threads to be Whitworth, the area of one bolt at the bottom of the thread is equal to .304 sq. inches; therefore, the combined area of the bolt fastening will be $4 \times .304 = 1.216$ sq. inches. Allowing a safe working stress of, say, 7,000 pounds per sq. inch, we get $7,000 \times 1.216 = 8,512$ pounds. The surface supported is $13 \times 13 = 169$ sq. inches, and this divided into 8,512 pounds, thus $8,512 \div 169 = 50.37$, or the working pressure in pounds per sq. inch that can be carried.

READERS' QUERIES

1—What horse-power is required to operate an air compressor with cylinder 16 in. in diameter by 24 in. stroke, discharging at both ends against a pressure of 90 pounds per sq. inch? A belt flywheel, 12 ft. in diameter, is the driving medium, and the revolutions are 100 per minute.—A. R. P.

* * *

2—What is the refrigerating capacity of a double-acting ammonia compressor whose cylinder is 8 in. in diameter and stroke 16 in. when running at 100 r.p.m.? The piston rod diameter is 2 inches.—A. S.

* * *

3—How many tons of work are performed by an ammonia condenser using 300 Imperial gallons at 60 degs. F., the final temperature of which is 90 degs. F.?—A. S.

* * *

4—How many tons of work result from pumping 160 U. S. gallons of brine per minute through a brine cooler? The temperatures of the ingoing and outgoing brine are 15 degs. F. and 35 degs. F. respectively.—A. S.

* * *

5—The temperature of liquid ammonia is 84 degs. F., and the temperature of brine in the cooler is 2 degs. F. The liquid in order to evaporate must first be cooled from 84 degs. F. to 8 degs F. The cooling takes place right behind the expansion valve, where part of the liquid evaporates and extracts the heat from the remaining liquid. What is the percentage of loss due to cooling the liquid? The latent heat of the liquid at 80 degs. F. is 560.5 B.t.u.—A. S.

* * *

6—A suction pipe, not insulated, passes through a room whose temperature is 60 degs. F. As the pipe must be frosted to deliver saturated gas, a loss is the result. How many B.t.u. are so lost in condensing and freezing one pound of moisture on the pipe?—A. S.

HYDRO-ELECTRIC MEMORANDA

ONE Imperial gallon contains 277 cubic inches of fresh water.

One Imperial gallon contains 10 pounds of fresh water.

One U. S. gallon contains 231 cubic inches of fresh water.

One U. S. gallon contains 8.33 pounds of fresh water.

One cubic foot of fresh water at 62 degrees Fah. weighs 62.55 pounds.

One cubic foot of fresh water at 62 degrees Fah. contains 7.48 U. S. gallons.

One cubic foot of fresh water at 62 degrees Fah. contains 6.23 Imperial gallons.

Water is at its greatest density at 39.2 degrees Fah., at which 1 cubic foot weighs 62,425 pounds.

2.31 feet depth of fresh water at 62 degrees Fah. will produce a pressure of one pound per sq. inch.

Height of column of water divided by 2.31 will give pressure in pounds per sq. inch.

Pressure in pounds per sq. inch due to a column of water multiplied by 2.31 will give the head in feet.

One Imperial gallon of fresh water raised 1 foot high equals 10 foot pounds, therefore 100 Imperial gallons raised 50 feet high equals $10 \times 100 \times 50$, equals 50,000 foot pounds.

One U. S. gallon of fresh water raised 1 foot high equals 8.33 foot pounds; therefore, 100 U. S. gallons raised 50 feet high equals $8.33 \times 100 \times 50$, equals 41,650 foot pounds.

The British thermal unit (B.t.u.) or Joule's equivalent of heat, is 772 foot pounds, and represents the energy necessary to raise one pound of water 1 degree Fah. when at or near its point of greatest density, 39.2 degrees Fah.

One horse-power equals 33,000 foot pounds per minute.

One horse-power divided by $772 = \frac{33,000}{772} = 42.74$ B.t.u. per min.

One horse-power equals 746 watts.

One kilowatt equals 1.34 horse-power.

One kilowatt equals 1,000 watts.

BELT PULLEY NOTES

IN determining what pulleys are best to use in any equipment, the factors of windage, weight, balance, belt contact, powerful compression to avoid keyseating of shaft, and convenience of handling should each have consideration. A choice of pulleys which fulfils these requirements may mean a somewhat high initial outlay, but will mean annually much reduced operating expense.

Pulleys as manufactured are of cast iron, wrought iron, mild steel, wood and iron or steel in combination. For good belt contact, minimum slippage, and least power absorbed without undue recourse to belt dressings to secure adhesion, the wood rim is to be commended. It should, of course, be borne in mind that there are good and bad features in wood pulleys. Belt contact, reduced weight, and facility of handling, are, generally speaking, strong points in their favor, but unless at least the equivalent windage of a well-designed cast iron pulley be had, the other gains may be partly offset. The properly designed wood pulley should be the equal of other types in their best features, and their superior otherwise.

An absence of windage is not always a feature of wood pulleys. The improvement necessary in the reduction or absence of windage in wood pulleys lies in the arm attachment between rim and hub. The arms should be of a shape corresponding to those in cast iron or similar; the material light, rigid, reliable, and attached securely to rim and hub.

The wood pulley has advantage over those of iron or steel, in that it can be run at a much higher speed.

The outer face of a belt travels faster than the inner, causing compression of the latter and extension or stretching of the former. This process has a naturally injurious effect on the substance and life of the belt and should be minimized to the fullest extent possible by using large diameter pulleys, those especially with little crown. Horizontal shaft pulleys should have about ⅛ inch per foot crown, while those on a vertical shaft should have about twice that amount.

Installation of Belting

In applying new belts, care should be taken that the proper side goes next to the pulley. Belts have what is known as a flesh and a hair face; the former of which to the uninitiated might suggest itself as the driving face. This is not so, however, for the reason that the flesh face being tougher, is better able to stand the stretching already referred to, and the hair side which is predisposed to cracking, wears better under compression.

The top end of splices connecting the laps should point in the running direction of the belt. Horizontal belts and angle drives up to 45 degrees from the horizontal plane, should have a sag of about ⅛ inch per foot, and the underside be the driver. Vertical belts should be pulled tight to ensure grip on the lower pulley. Shafting and machinery should be so arranged that belts will run from the former to the latter in opposite directions to equalize the strain and pull on the bearings. Increase of belt width should mean a corresponding increase in thickness, and it is probably true that a thick and narrow belt is more durable and works rather more satisfactorily than does one wide and thin.

Flapping of belts is due to a variety of causes, to which the following are the chief contributors; the ends of the belt at the joint not being perfectly square, pulleys out of line and set at an excessive distance between centres, high velocity running which tends to trapping of the air between belt and pulley, thereby diminishing the adhesive contact. Sudden and often occurring change of speed due to heavy intermittent machine load, invariably causes flapping of belt. Trapping of the air may be counteracted by perforating the pulley rim or the belt.

TWIN STRAINERS

A type for every condition

The requirements for strainers are so wide and varied that no one type will meet all conditions, but from the many types of Twin Strainers, some one type can be selected that is particularly suited for any condition.

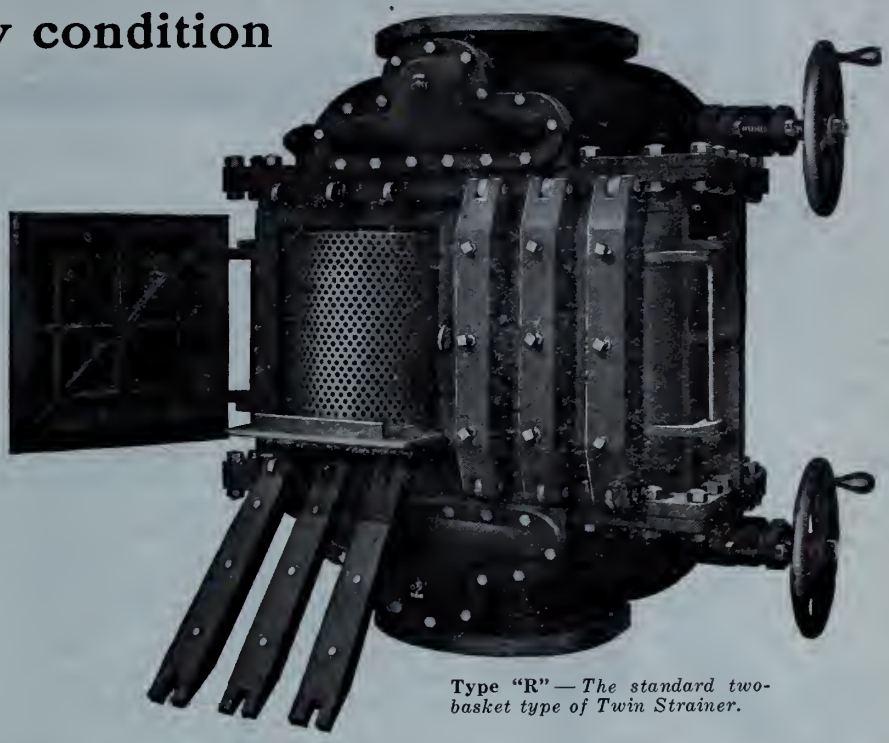
The main principle of all types of Twin Strainers is the Twin (two-in-one) feature. This feature means that when one side of the strainer is being cleaned, the other side is ready to take its place. Just move two valves—and the clean strainer replaces the dirty one—dirty because it's been doing its duty, collecting solid matter from the liquid passing through the strainer.

Twin Strainers will handle water, oil, or any other liquid, and can be installed anywhere—wherever it is most convenient.

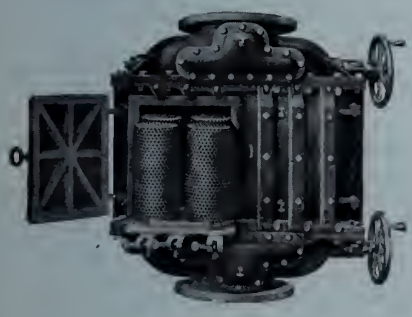
Write for Bulletin "A."

ELLIOTT COMPANY

6902 Susquehanna Street
Pittsburgh, Pa.

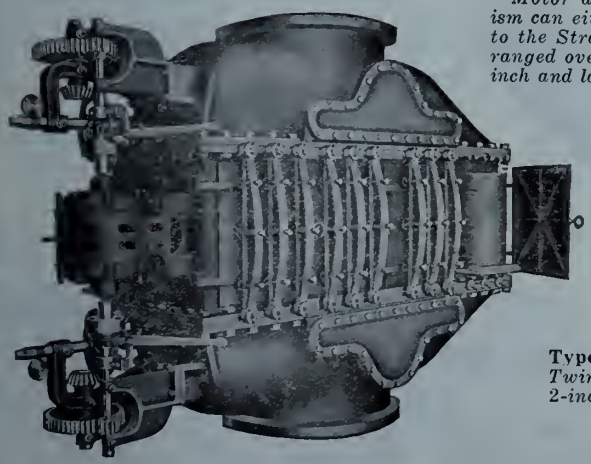


Type "R" — *The standard two-basket type of Twin Strainer.*

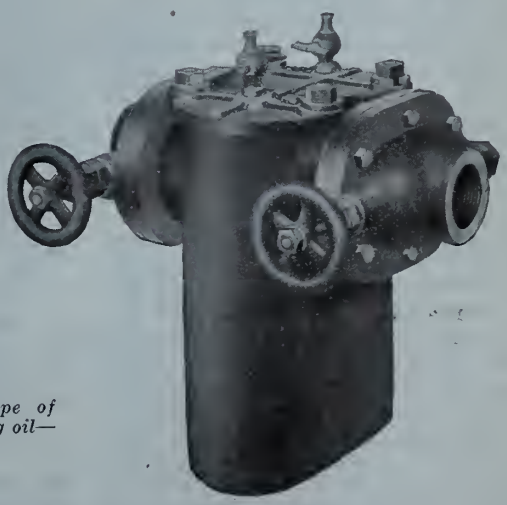


Type "S"—*(on the left) Suitable for use where the liquid to be strained contains large quantities of solid matter, or where it is desirable to use baskets with fine perforations.*

Type "T"—*(on the right) A special type of Twin Strainer for* 150-*lb. working pressure*—16, 20 *and* 24-*inch sizes.*



Motor operated Twin Strainer —*Motor and operating mechanism can either be attached direct to the Strainer as shown, or arranged overhead, as desired*—30-*inch and larger sizes.*



Type "U" — *A special type of Twin Strainer for straining oil*— 2-*inch and smaller sizes.*

Steam Power Plant Auxiliaries

BOILER FEED REGULATORS—II.

THE flexibility possessed by some types of boiler together with the occasional desirability of reducing the water level in proportion to the load carried suggested the idea of producing a device which would enable such operating conditions to be automatically obtained. The development of the idea was

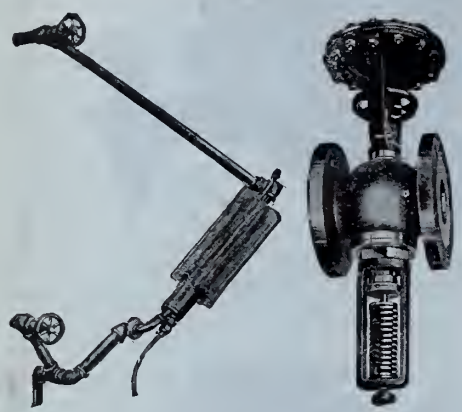


FIG. 3. LEFT, GENERATOR OF "S.-C." REGULATOR. RIGHT, REGULATING VALVE OPERATED BY GENERATOR.

doubtless further prompted by the customary method of locomotive operation, whereby it is usual to raise the water level to the safe high limit before reaching any particular grade. When climbing the grade, the rate of feed is reduced or sometimes discontinued for a short period so that all the heat from the furnace may be spent in making steam and none in heating feed water. The variable type of feed-water heater duplicates in stationary practice that which was found advantageous in locomotive practice, and also provides a uniform rate of feed at any particular level, provided the load is also uniform. In other words the greater the load the lower the level, with correspondingly drier steam and reduced risk of priming.

'S'-C" Regulator

This apparatus possesses as its source of motive power, a certain fixed quantity of water in a closed system, the pressure of the liquid varying with the amount of heat imparted to it through variations of the water level. It is designed to give a continuous graduated feed, increasing as the level decreases, and decreasing as the level rises until at high level it shuts off the feed entirely. Figs. 3 and 4 show the appearance and construction of the device which consists of a generator R, a regulating valve in the feed pipe (not shown), and a hydraulic tube M, connecting the generator with the regulator.

The generator is installed on the same level as normal water level in the boiler and is adjustable to various angles so that the vertical height from top to bottom of generator may vary from 2 in. to 8 in. Through the generator passes a ⅛ in. tube D, which is in series with the steam and water connections, but which does not communicate with the internal space of the generator. The only connection into the generator is the tube M from regulator, and the entire system of generator, tubing and regulator is filled up with water and sealed with plug I. The level of the boiler water in the ⅛ in. tube D will now rise or fall with the boiler. The water in the generator, however, is being cooled all the time by radiation through the extenrnal fins, and kept below boiling point, while a portion of tube D is filled with steam at boiler pressure and tends to heat up the upper part of the water in the generator. According as the boiler level falls, so will more of the tube D heat up the generator and increase the pressure so that the feed pipe regulator will be opened correspondingly more.

The sectional illustration, Fig. 4, shows

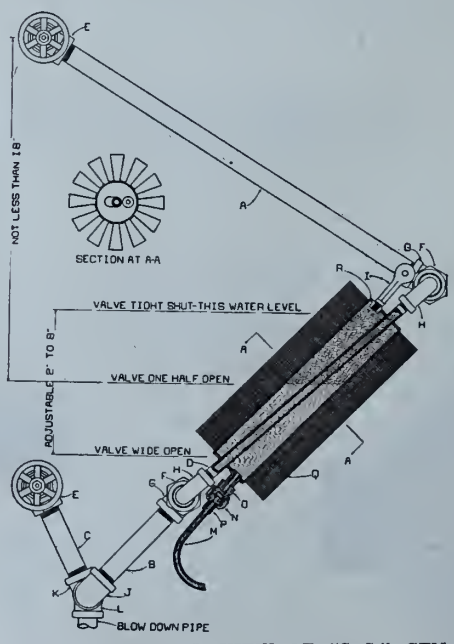

FIG. 4. SECTIONAL VIEW OF "S.-C." GENERATOR SHOWING CONTAINED FLUID UNDER PRESSURE.

the condition of the generator liquid when the boiler level is half way down. The upper portion is changed into steam and maintains a constant pressure in the controlling system; while, if the boiler level rises, the valume of steam decreases with the decreased amount of

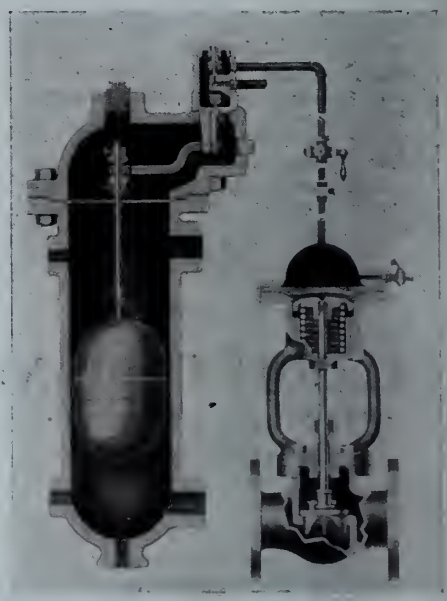

FIG. 5.—SHOWING ARRANGEMENT OF "ELLIOT" FLOAT OPERATED FEED REGULATOR WITH CONTROLLING VALVE.

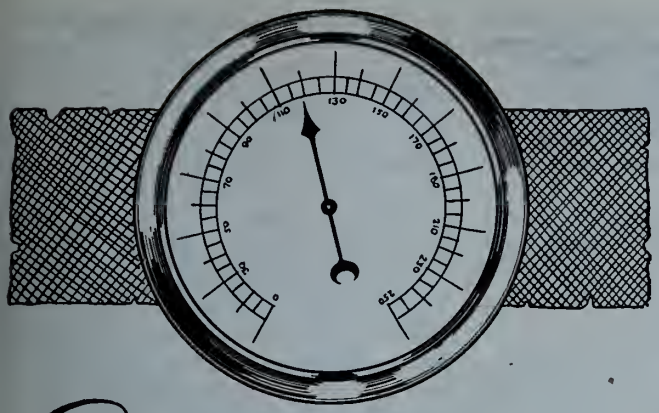
steam in tube D until, at the high limit, the feed is closed off completely.

The flexible fittings used allow of the "S-C" regulator being adjusted when the boiler is in operation, and by varying the vertical height referred to the limits of the boiler level may be set to suit a particular type of boiler. The system so operates that on an increasing load it will always feed at a lower rate than boiler output until peak load level is reached, and on a decreasing load it will feed above the boiler output until light load level is reached. The only time the regulating valve will close is when there is no load.

This apparatus is manufactured by the "S-C" Regulator Co., Fostoria, O.

Elliot Regulator

The objects aimed at by the designers of this regulator are reliability, accessibility, least number of working parts, and ability to make adjustment under full steam pressure. Illustrations Figs. 5 and 6 show one of the designs, which is characterized by the use of a long body water column and a diaphragm type of controlling valve. In actual operation, their relative positions are changed, as the water column is mounted on the boiler, and the controlling valve is located in



Can you keep the pointer where it belongs?

It's getting near four o'clock. The demand for power is a trifle heavier than usual. The peak is coming. The sockets click one after another in a steady stream. The demand for steam is going up, up, up. Can You Keep The Pointer Where It Belongs?

Sturtevant
(TRADE-MARK)

Turbo-Undergrate Blower

will keep steam up. It supplies all the draft you want and just when you want it.

When you buy a blower be sure it's a Sturtevant. The Sturtevant name is a guarantee of mechanical excellence—a guarantee that you will have no breakdown and no bearing trouble. The Sturtevant Set has generous bearings with oil rings and large reservoirs. One filling will last for weeks.

To prevent the escape of steam from the casing there is a floating stuffing box. If for any reason through neglect or carelessness this is allowed to leak, there is a special "water-throw" collar which makes it impossible for steam to enter the bearings. Furthermore, the floating stuffing box makes it possible to exhaust against back pressures as high as 25 pounds.

If you have trouble getting enough steam or keeping the needle where it belongs, write us for bulletin No. 214-U.

any convenient place in the feed line.

The regulating device consists of a float operated pilot valve, which operates with the fluctuations in the water level and causes the controlling valve to be closed or opened, depending upon whether the water level is above or below

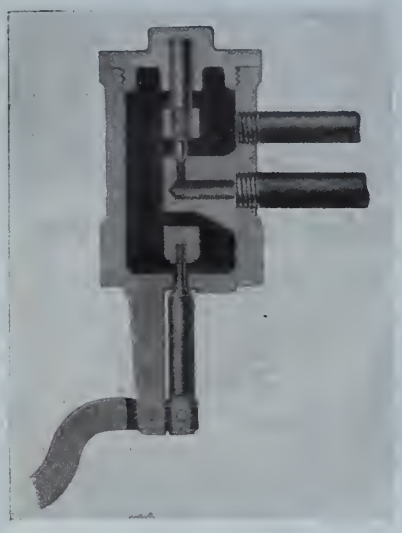

FIG. 6.—ENLARGED VIEW OF PILOT VALVE OF "ELLIOT" REGULATOR

the normal. The pilot valve is shown in detail in Fig. 6, the chamber which contains it being mounted on the top of the water column. An arm extends downward from the chamber and supports the float lever.

The pilot valve is of the double type, the upper valve which controls the exhaust to atmosphere being carried in a yoke, which in turn is mounted on the stem of the lower or steam valve. The exhaust valve is guided on its upper end by a cap which closes the chamber, and which can be removed to enable adjustment of the valve to be made after long service. The upper pipe from the valve chamber, as shown in Fig. 5, is connect- to the diaphragm chamber of the controlling valve.

Assuming the water level in boiler to be above normal, the float rises and lifts up the long arm of the lever, thus opening the steam valve downward and closing the exhaust valve on top. The diaphragm chamber which is filled with water is now under boiler pressure, and the controlling valve spindle is forced down till the valve is closed and the feed stopped. As the water level begins to drop, the weight of the float is gradually transferred to the lever until the weight of the float overcomes the steam pressure which holds the exhaust valve on its seat. When the exhaust valve is unseated, the weight of the float seats the admission valve, and the steam that is contained in the chamber and pipe line passes through the exhaust valve to atmosphere, relieving the pressure and allowing the controlling valve to be opened by the spring provided for that purpose.

As the water level again rises in the boiler, the float has a tendency to rise, but the pressure of the steam on the admission valve keeps it closed until the float has acquired sufficient buoyancy to lift the lever when the cycle of operations is repeated. With ordinary boiler pressures, the necessary buoyancy of the float is obtained with not more than ⅝ in. variation in water level, while the construction of the pilot valve chamber enables adjustment to be made under full steam pressure.

These regulators are made by the Elliott Company, Pittsburgh, the various types being suited for use on water tube and fire-tube boilers of all types.

Foster Regulator

This regulator is of the intermittent type and depends for its action on the alternate expansion and contraction of a length of tube which is filled with steam or water, according to the variation of water level. Its action is slightly different from those regulators which depend on the buoyancy of floats or other bodies, as the time necessary for its coming into action depends on the speed with which the expansion tube radiates its heat. The resulting lapse of time between the change of level and action of the regulator allows it to remain longer in each position with less frequent opening and closing.

As illustrated in Fig. 6 the expansion tube 1 is screwed into the main bracket 2, in which are also fixed two guide rods 4. The upper ends of rods 4 are tied with a bracket 6 on which is hinged a bell crank 8, the short arm of which rests on top of adjusting screw 9 in the upper end of expansion tube. At the lower ends of rods 4 is clamped a bracket 11 which carries bell crank 10, one arm of which is flexibly connected to the long arm of bell crank 8, while the other arm extends horizontally and engages with the stem of the regulating valve 14. Positive closing of this valve is insured by an ad-

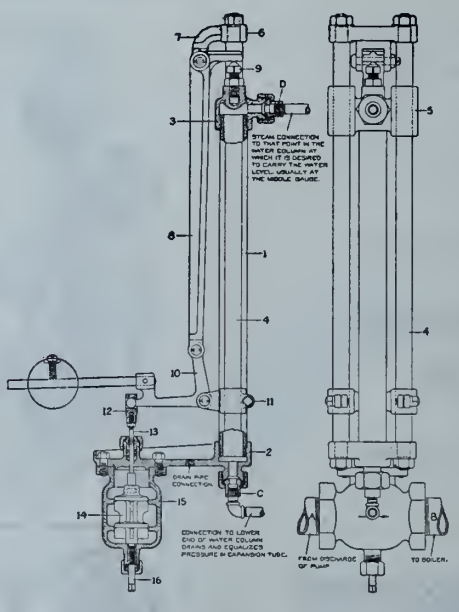

FIG. 7. "FOSTER" REGULATOR WITH EXPANSION TUBE AND MECHANICALLY OPERATED CONTROLLING VALVE.

justable counter weight carried on an extension of the bell crank arm.

The alternate admission of steam and water to the expansion tube is obtained by the method of connecting up the two ends C and D to the boiler. The expansion tube is first of all located at a point completely above the high level of the water in the boiler, after which connection C is carried to a point below the desired level, and connection D to a point just at the desired height of the water level in the column. Whenever the water level falls below connection from D, the expansion tube will be filled with steam, as its lower end is also above water level. The expansion due to the heat of the steam causes adjusting screw 9 to raise the short arm of the upper bell crank, so that the long arm moves over toward the expansion tube and opens up the regulating valve by means of the lower bell crank. The feed gradually attains a maximum as the expansion tube gets hotter, and remains so until the water level rises high enough to close connection from D. Water will now enter both ends of the expansion tube, replacing the steam which condenses as the heat is radiated, and causing tube to contract, so that the feed regulating valve is allowed to close, due to weight of ball on rod, which also causes the short arm of upper bell crank to follow down in top of adjusting screw as the expansion tube contracts.

While a very small variation of water level is sufficient to operate this device, the time necessary for the tube to warm up and cool down, causes less frequency of operation than with certain other intermittent types. There is an entire absence of stuffing boxes, the whole action is mechanical and therefore positive, and the position of the counterweight ball indicates instantly whether the feed valve is open or closed. This regulator is made by the Foster Engineering Co., Newark, N.J.

Economiser Explosions.—The idea that an economiser is safe from explosion because it is only exposed to water pressure is probably due to the fact that vessels which have to be worked under steam or air pressure are invariably tested by means of water. The reason for so doing is that danger is eliminated of the parts flying violently asunder should any part fail, as would happen if steam or air were employed. There is, however, a great difference between an economiser under pressure and a steam boiler or other vessel under cold water pressure. In the latter case, in the event of any part of the structure failing, the pressure is instantly relieved, with very little increase in the volume of the fluid, and no great harm is done; in the former case much of the water in the economiser is usually at a temperature much greater than 212 deg. Fah., so that should the pressure be suddenly relieved due to failure of the containing vessel, a portion of the water would immediately flash into steam, the accompanying violent expansive force of which may cause entire disruption of the economiser.

GRATON & KNIGHT

Standardized Series LEATHER BELTING

Tanned by us for belting use

GRATON AND KNIGHT

Are you trying to drive Pulleys with a Belting Specification?

How often does a belting specification get you the kind of belts you really should have? Do the belts you get agree with the specification? How many men in your plant could tell? Could **you?**

The only specification the belt buyer should attempt to make is a specification of the work to be done. Because to get the work done most efficiently and economically is the only possible reason for any kind of a specification about anything.

Graton & Knight offer you this practical specification—the work to be done. To do the work properly in every case is the basic idea underlying the Graton & Knight Standardized Series Leather Belts.

This Series was evolved to fit the working needs of actual conditions, *not* to meet theoretical conditions as described on paper. Every belt in this Series—and there is one for every transmission purpose—has been standardized only after it has been *proved* right.

Face these facts squarely—then consider the safety, ease and economy of buying Graton & Knight Standardized Belts. Not by guesswork, nor on discount—but on *standardized performance*.

Write for a description of Graton & Knight Belting Standards and a copy of their Book on Belting.

VERTICAL STYLE

Sweet's Steam and Oil Separators in all Styles and Sizes.

WATER IN STEAM

With the small clearances now allowed in reciprocating engines, water in steam in small bodies will break either the valve, cylinder head, or piston, or may break all three and cause a general wreck costing hundreds of dollars; in smaller but continuous quantities it will cut out valves, seats and cylinders, necessitating renewals. Water in steam fed to turbines cuts out the blades very rapidly. More cylinder oil is required with wet steam, and there is a constant loss by its use, in efficiency, due to increased initial condensation.

A good separator cures these troubles—a poor one just nibbles at 'em. Let us send our story.

ONE HORIZONTAL RETURN TUBULAR boiler 78" diam. 18' long, good for working steam pressure of 105 lbs.

One new 60" x 14' horizontal return tubular boiler passed and stamped for a working steam pressure of 134 lbs.

One 60" x 16' horizontal return tubular boiler passed and stamped for a working steam pressure of 70 lbs.

One 60" x 14' horizontal return tubular boiler good for a working steam pressure of 90 lbs.

One 35 H.P. locomotive fire box boiler passed and stamped for a working steam pressure of 90 lbs.

All above boilers complete with all usual boiler fittings.

One 15" x 34" Wheelock Engine, right hand.
One 11" x 28" Wheelock Engine, right hand.
One 22" x 48" Wheelock Engine, right hand.
Roofers' tar kettles carried in stock.

LEVY & WESTWOOD MACHINERY CO.,
Toronto.

Port Arthur, Ont.—The Port Arthur Pulp & Paper Co. have awarded a contract to the Storey Pump & Equipment Co., Toronto, for two 10 x 6 x 12-inch "Deane" duplex, end packed plunger boiler feed pumps.

Oshawa, Ont.—The Town Council have given the first and second reading on a by-law to authorize an expenditure of $38,000 on a filtration plant. The John Ver Mehr Co., of Toronto, have already been awarded a provisional contract.

The Bawden Pump Co., Toronto, have been awarded a contract by Fraser's, Ltd., Edmunston, N.B., for 14 centrifugal pumps of from one to four million Imperial gallons daily capacity, and also a compound boiler feed pump. This equipment is for a new pulp and paper mill.

Oshawa, Ont.—The Town Council have awarded a contract to the Turbine Equipment Co., Toronto, for one 6-inch 2 stage, De Laval centrifugal pump, to have 1½ million gals. a day against 340 ft. total head, and to be direct connected to 150 h.p. motor.

The Storey Pump & Equipment Co., Toronto, have recently been awarded the following contracts: Two 4 in. double suction Morris centrifugal pumps for the Swift Canadian Co., Toronto; two 4-stage Morris turbine pumps for Gravenhurst, Ont.; one 4 in., 4-stage Morris turbine pump for the Canadian Copper Co., Sudbury, Ont.

The Turbine Equipment Co., Toronto, have been awarded a contract by the Imperial Oil Co., Ltd., Sarnia, Ont., for two-De Laval 14 in. single stage centrifugal pumps, each having a capacity of 9 million gals. a day against 108 ft., total head. Each of them will be direct connected to Canadian Westinghouse 225 h.p. motors.

Belleville, Ont.—The Town Council have awarded the following contracts to the Turbine Equipment Co. of Toronto. One-De Laval 6 in. 2-stage centrifugal pump, direct connected to a 150 h.p. motor, having a capacity of 225 million gals. a day against 250 ft. total head. Two-De Laval 6 in. 2-stage pumps. One to have a capacity of 1¾ million gals. a day against 250 ft. total head, and to be direct connected to 125 h.p. motor, and the other to have a capacity of 1,100,000 gallons per day, and to be direct-connected to a 100 h.p. motor.

The Galt Foundry Co., Galt, Ont., have recently closed contracts for a large number of their Galt Sprinkler stokers to the order of many prominent concerns, some of which are included among the following. The T. Eaton Co., 3-stokers at Toronto and 12 at Winnipeg; Dryden Pulp & Paper Co., Dryden, Ont. 12 stokers; Hinde & Dauch Paper Co., Tor-

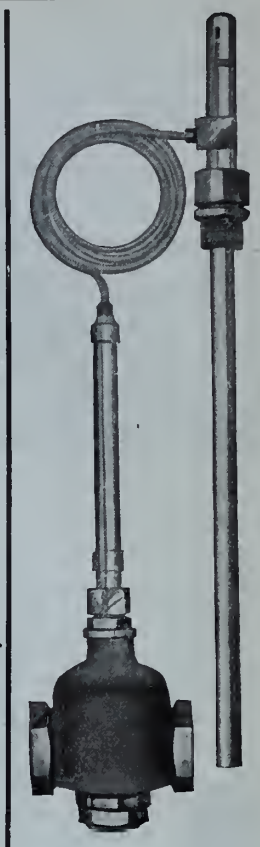
Too Hot? Too Cold?



Use a Sarco Temperature Regulator and get your conditions right.

If you want to keep your product at any temperature between freezing point and 325° F., you can install a Sarco Regulator and control your heating or cooling medium so as to use just as much or as little as you need. There is no waste and your product will be better and more reliable because produced under standardized conditions.

The Sarco Temperature Regulator is a tube containing oil. When this oil heats it expands; when it cools it contracts. This expansion and contraction becomes effective on a balanced valve which opens and closes, thus feeding or checking the heating or cooling medium so as to keep the temperature where you want it. No hand valve can be operated as sensitively—the SARCO is a thermometer plus a hand. It works twenty-four hours a day, is self-contained and supplies its own motive power.

You can have one on 30 days' trial. Ask for a pamphlet on Sarco Temperature Control and say whether you want to control a water, gas or steam supply.

VICTORY
NATIONAL SERVICE
THE RIGHT WORK AT THE RIGHT PAY

After the war—*What?*

Few can predict—yet all can prepare! Our present prosperity rests in part on an artificial basis which peace must remove. Now is the time to consolidate your position by regulating your expenditures—by husbanding the surplus—and by investing to the limit in Canadian War Loans, that help so much to maintain present prosperity.

The National Service Board of Canada

This space is donated by MacKinnon, Holmes & Co., Limited

onto, 8-stokers; Spanish River Pulp & Paper Co., Sturgeon Falls, Ont., 4 stokers; Hamilton Cotton Co. 6 stokers; Dominion Power & Transmission Co., Hamilton, 3 stokers; City of Brandon 2 stokers and Dominion Oilcloth Co., Co., Montreal, 4 stokers.

Montreal, Que.—After a conference with the consulting engineers, Messrs. Vautelet, McRae, & St. Laurent, the Board of Control resolved to instruct the chief engineer to prepare plans showing the modifications required according to the engineers in projects 2, 4 and 5 of the aqueduct. It was further resolved by the board to instruct the chief engineer to prepare specifications for the supply of electricity for pumping purposes. The board also decided to get comparative information on buying electric power for pumping by hydraulic power, with the present project modified, as suggested by the said engineers.

CATALOGUES

Rubber Belting.—Booklet issued by the Goodyear Tire & Rubber Co., Toronto, contains a standard rubber belting price list and a list of firms using this concern's goods.

Air Compressors.—The CanadianIngersoll-Rand Co., Montreal, have issued a new bulletin describing their class FL-1 steam-driven, single stage, straight line, air compressor. The construction and principal features of this machine are described fully, accompanied by detail illustrations and general views.

Pipe Threading Machinery, made by the Landis Machine Co., Waynesboro, Pa., is the title of catalogue No. 23, just off the press. This catalogue illustrates and describes in detail the Landis stationary pipe die head, pipe threading and cutting machines, pipe and nipple threading die heads, pipe and nipple threading machines, and the Landis chaser grinders. The catalogue sets forth the distinctive features of the Landis product, and also contains specifications covering the various types of machinery described. A detailed list of parts is also included.

Air Compressors.—Bulletin K-302, 16 pages 6 x 9 in. illustrating a line of steam driven, straight line, single stage air compressors manufactured by the Canadian Ingersoll-Rand Co., Ltd., of Montreal. The type of machine described is designed to cover the field of those requiring compact, self-contained units of small and medium size for service in shop, foundry, mill or electrical plant, etc. Automatic splash lubrication, dustproof construction, "Circo" silent leaf valves and quick convertibility to melt drive are among the leading features of the design dwelt upon in this publication.

The "F. M. Book".—Even those best acquainted with the Canadian Fairbanks-Morse Company will be surprised at the very wide range of goods shown in their new general catalogue which they have called the "F. M. Book". This book is a marvel of complete mechanical information condensed into a convenient size for easy reference. It contains 1048 pages, and over 4670 illustrations.

It is, in fact, a key or index to the vast warehouses of "Canada's Departmental House for Mechanical Goods" and contains a very wide selection of "Made in Canada" Goods.

Twelve distinct departments are represented, each department covering a line of goods which is ordinarily considered a business in itself.

The scale department (52 pages) covers a full line of Fairbanks Scales.

The valve and steam goods department (138 pages) contains 42 pages of valves, and 96 pages of pipe, fittings, steam specialties and tools.

The automobile accessory department (140 pages)—here you will find every practical accessory for automobile, Ford and otherwise, besides a complete line of motor boat fittings.

Engine department (16 pages) and electrical department (22 pages). These pages are merely an index of the various styles of Fairbanks-Morse oil and gasoline engines, electrical generators and motors. Complete descriptive bulletins of this apparatus will be sent on request.

Pump department (62 pages). Here is shown a very complete line of steam, power and hand pumps, duplex, triplex and centrifugal, besides a number of pump accessories and windmills.

Machine tool department (110 pages). Nearly every type of machine tool is represented; among them some of the best known machine tools on the Continent. Truly a representative department.

Wood working machinery department (88 pages). As fully representative as the machine tools.

Transmission department (86 pages). Every appliance for transmission of power through belts, ropes, chains, conveyors, etc., is here shown.

Railway and contractors department (100 pages). Containing railway track tools, motor cars, road machinery, trucks. etc.. etc. A very interesting section.

Supply department (138 pages). Representing a line of tools and supplies for equipping any factory.

Safe and vault department (26 pages). Showing a line of high grade fireproof safes and vault fronts.

In addition to all this is a 64 page section, printed on yellow paper, and containing beside, an excellent index, a quantity of tabulated information most commonly used.

A copy of the "F. M. Book" will be sent free to any one interested in mechanical lines, on receipt of their request.

Cameron Babbitt Retainer
(Patented in Canada and the U.S.A.)
Not like clay or other material, as it does not stick to the work or hands. Does away with using leather or paste-board at end of box.
The only satisfactory compound for retaining molten metal and can be used over and over again for months—no deterioration.
For any metal.
For prices and samples apply to
A.S.K. Chemical Company, Elora, Ontario

Where metallic materials have to be cut or united, as in the case of boiler mending, or where broken castings have to be reclaimed, a big saving in time and money, a more efficient job is assured by the use of—

Davis Acetylene Pressure Generators

They represent the most advanced ideas in Oxy-Acetylene Welding, recognized among the world's foremost inventions of this generation. It is revolutionizing the manufactures of metal products, of steel cutting, and the methods of repairing broken and worn metal parts, light or heavy.

We do all kinds of Oxy-Acetylene Welding with the Davis-Bournonville Outfits. Shops where a fair amount of work is done should do their own welding. They will find it most profitable and convenient. We handle Davis-Bournonville outfits and plants, big and small, and give your operator a thorough training course when we make an installation.

Don't lose any time—investigate now. Write for full particulars.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways.
W. C. McGHIE, Chairman of Board.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

12 x 12 Side Crank, Robb Armstrong Engine direct connected to G. E. direct current generator. 50 KW. 290 R.P.M. 500 Volt. Switchboard complete. Also 1—40 H.P., D. C., C. G. 500 Volt. 975 R.P.M. Motor.

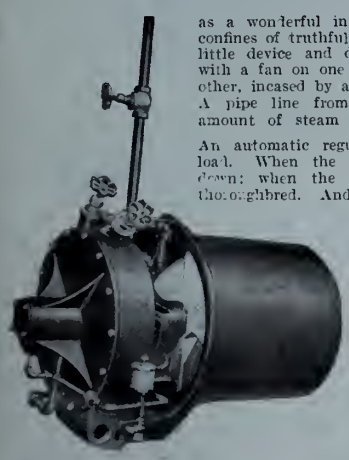
We guarantee this equipment to be in first class condition.

THE AULT & WIBORG CO. OF CANADA
LIMITED
CHARLOTTE STREET - TORONTO, ONT.

"Doing Our Bit"

We believe we are "doing our bit" in demonstrating to manufacturers how they can effectively cut down the cost of steam production, better their combustion and increase the capacities of their boilers. In offering the

Coe Turbine Blower



as a wonderful invention, we are well within the confines of truthful advertising. It is such a simple little device and does such a big work! A shaft with a fan on one end and a steam turbine on the other, incased by a shell is about all there is to it. A pipe line from the leader supplies the small amount of steam required.

An automatic regulator adjusts the speed to the load. When the load is light, the blower slows down; when the peak comes it responds like a thoroughbred. And how it does drive the air into the fire! Clinker doesn't get a chance to form.

The gases of combustion which ordinarily pass up the chimney are held back by the draft controller, thoroughly mixed with the air and burned. Nothing gets away that is worth keeping.

Space limits prevent a complete description of the Coe Turbine Blower. Write for it and receive our special demonstration proposition. You should have it. We solicit your inquiry.

C. T. COE COMPANY
Engineers and Combustion Experts

The Harland Engineering Co., Montreal, Que.

Efficient Fuel Burning Demands Intelligent Draft Control

We don't need to emphasize the *importance* of correct draft control. That's pretty well understood by every power plant man—*now* more than ever. In fact, correct draft control bears so close a relation to the *coal pile* that a good many engineers who depend on "judgment" for draft regulation naturally *worry about* it. The *better way* is to install a

PRECISION
3-in-1 Gage

PRECISION 3-in-1 Air Gage

and *stop guessing*—and worrying.

You *know* what your draft conditions are with the "3-in-1." You know when air pressure is low or high, and *where* it is low or high — at the Damper, the Combustion Chamber or the Ash Pit. You know just *how* to regulate it and how *much*. The results—in coal consumption—will surprise you. Write for facts and service data.

Wasted Power
AND
Wasted Labour

YOU cannot afford to waste power or labour and if you could, it would be folly or a crime to do so. You can save both by installing "Bennis" Machine Stokers and Automatic Coal Elevators and Conveyors.

Illustrated catalogues free on request.

To Get Longer Service From Generators — Protect them against excess heat under over-loading conditions by applying a

FOXBORO
TRADE MARK

RECORDING THERMOMETER

With Electric Alarm Attachment.

This instrument enables you to watch carefully the temperature effect of high loads, to load your generator to the maximum, to check daily operations and load conditions.

Overheating and possible burning is prevented by alarm attachment.

Drop us a card for Bulletin No. B.H. 96.

Large Stocks carried in Canada by

Low Water Alarm

The distinct feature about this water column is its alarm when too much or too little water is in the boiler. You know the relief a feature of this character will give you. The certain knowledge that when the quantity of water becomes dangerous a whistle will blow.

Besides this feature the Anderson Water Column is built in such a manner that the maximum service is given.

The V. D. Anderson Co.

1935 West 96th St.

OILS

These Lubricants give remarkable service. They will keep your machinery running smoothly, easily and with a minimum of wear and cost.

No better time than now to put them to the test. The prices are very reasonable.

Potato Scale Powder Boiler Cleanser

Will positively rid your boilers of old scale and will *keep* tubes clean if but a small amount is fed daily through the feed water.

Eliminates foaming, pitting or any other boiler troubles due to impurities in the water supply. *Makes big reduction in fuel bills.*

Sold UNDER A POSITIVE GUARANTEE. Try a Barrel.

WINNING THE BUYER'S FAVOR

THE best possible buyer is not made an actual buyer at a single step It is one thing to win the buyer's favor for an article and another to make adjustments incident to closing the sale. Winning the buyer's favor is the work of trade paper advertising. Under ordinary conditions it should not be expected to do more.

MacLean's for August

An illustration by Ben Ward for "Mam'selle Butterfly" in August MacLean's.

Is a Midsummer Number

AN August magazine will be read by most people when the languor of summer heat possesses them, when entertainment more than heavy stuff is most welcomed. Yet something worth while in the way of special articles is desired—this by the thoughtful few.

The August MACLEAN'S is excellently balanced, as you will see from these contents:

CONTENTS

Frenzied Fiction for the Dog Days—(Done by the Dipperful.) By Stephen Leacock.

The Human Side of Conscription. By H. F. Gadsby.

Winning the War in the Air. By Agnes C. Laut.

A Circus Story. By L. B. Yates.

Mam'selle Butterfly. By Arthur Beverly Baxter.

The Captain of the Susan Drew. By Jack London.

An Andy Doolin Yarn. By Hopkins Moorhouse.

A Detective Story. By Robert E. Pinkerton.

The Gun Brand. By Jas. B. Hendryx.

Women and Their Work—A New Department. Review of Reviews—Regular Department.

Yates who writes the Circus Story, was born in Hamilton. He wrote those stories about Paragon Pete and The Singin' Kid in the Saturday Evening Post.

Leacock is excessively humorous in his Dog Days Sketch, in which he talks about summering and simmering.

Miss Laut fancies that the war may be won by the birdmen, and if Uncle Sam produces 100,000 planes, she may be right.

Gadsby sits in the Press Gallery at Ottawa, and writes brilliantly always. His "Conscription" article is in order.

Pinkerton who writes the detective story, "Old Twilight," knows how to write this class of story.

By the way, Lord Northcliffe has promised an article for the September MACLEAN'S.

You can see that MACLEAN'S for August is just the right type for August.

Another Recent Inglis Installation

Illustration shows our Horizontal Cross Compound Heavy Duty Corliss Engine recently installed in the new plant of the Canadian Kodak Company, Mount Dennis (near Toronto), Ont.

This ideal "Corliss" has cylinders 18 in. and 30 in. by 30 in. stroke, running at 150 r.p.m. It is direct connected to a 300 k.w. Canadian Westinghouse 3-wire, 125-250 volt, d.c. compound wound computing pole type generator.

The Engine operates on a steam pressure of 150 pounds, with 5 pounds back pressure. Valve Gear is operated by double wrist plates set for long range cut-off, the governor controlling both high and low pressure cylinders. Fly wheel is 11 ft. in diameter and weighs 22,000 pounds.

Put your Engine problems in our hands. Firms big and small all through Canada are doing so with the best of results. Tell us of your special requirements and Inglis Experts will go into the details immediately with you.

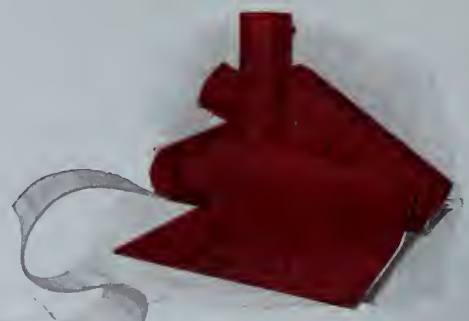
PEERLESS PERFECT PACKINGS

for Every Condition *and* Service



Try it to-day and learn just what Peerless Service means.

A KNOWLEDGE of conditions + combination of good materials = a good packing.

There is no one packing that will cover every condition in your plant any more than one coat will fit every man. For this reason the packing that might work on Jones' engine would not give service on yours although they were exactly the same.

Why?

Because the conditions in Jones' plant are different than in your engine-room. You don't care what packing will work in an engine one hundred miles away — you want a packing that will "do the trick" in your plant where you're on the job every day.

That is where Peerless Service comes in — we have over two hundred types and combinations of packings — each one designed to cover certain conditions. All you need do is send full particulars and we'll guarantee to give you service with a Peerless Packing.

WATEROUS RETURN TUBULAR BOILERS

In both Stationary and Portable types, Waterous Return Tubular Boilers are specially suitable for every industrial use. They combine economy in fuel consumption, ease and convenience in operation, with absolute trustworthiness.

"Safety First" is not new as applied to these Boilers—it has been the idea behind every detail of their design and construction for fifty years and more. Exceptional care—exceeding the requirements of ordinary Provincial boiler building regulations—has been consistently exercised in the selection of materials and in every operation of their building.

Let the next boiler you buy be a "WATEROUS."

The Metals That Win

"Nickle Genuine" has won the confidence of its users by its uniformity and its efficiency in use. Made for heavy duty machines, motors and dynamos It has established itself as a sure winner. 40 years' experience are manifested in its make-up. It must have merit to be the leader for so long.

"Frost King" Babbitt is indispensable to engines, pumps, rolling mills, pulp machinery or planing mills. It insures the highest efficiency of a machine. There is as much confidence in the users of this "King" of metals as its manufacturers put in it. An inquiry would obtain immediate attention.

WHY

worry because you cannot keep up steam pressure

WHEN

it is so easy and cheap to overcome your difficulties by installing a

COPPUS TURBO BLOWER

It means constant steam pressure, regardless of uneven loads, poor draft and poor coal, and it will pay for itself in a short time on account of better combustion. It also will increase your boiler capacity to 200, and even 300%, of its normal rating without injury to the boiler. Cut out this Ad., put your name and address on the margin and mail to us. Without further trouble you will get all the particulars.

500,000 H.P.

In boilers equipped with Coppus Turbo Blowers in four years. The Coppus has replaced a great many other blowers, but no other blower has ever replaced a Coppus.

"Doing Our Bit"

We believe we are "doing our bit" in demonstrating to manufacturers how they can effectively cut down the cost of steam production, better their combustion and increase the capacities of their boilers. In offering the

Coe Turbine Blower

as a wonderful invention, we are well within the confines of truthful advertising. It is such a simple little device and does such a big work! A shaft with a fan on one end and a steam turbine on the other, incased by a shell is about all there is to it. A pipe line from the leader supplies the small amount of steam required.

An automatic regulator adjusts the speed to the load. When the load is light, the blower slows down; when the peak comes it responds like a thoroughbred. And how it does drive the air into the fire! Clinker doesn't get a chance to form.

The gases of combustion which ordinarily pass up the chimney are held back by the draft controller, thoroughly mixed with the air and burned. Nothing gets away that is worth keeping.

Space limits prevent a complete description of the Coe Turbine Blower. Write for it and receive our special demonstration proposition. You should have it. We solicit your inquiry.

An "All Year" Saving!—

Users of the **MOREHEAD** "Back to the Boiler" **SYSTEM** for conserving steam heat, find that it is an all-year around economy. It works continuously—a daily saver of fuel—a daily help in the operation of the plant.

The efficiency of the plant is improved because of the function of the

Morehead Back to Boiler SYSTEM

delivering pure hot condensation back to the boiler under pressure as feed water—saves boilers, saves fuel.

MOREHEAD "Back to the Boiler" **SYSTEM** stands for economy—every day in the year.

Canadian Morehead Mfg. Co.

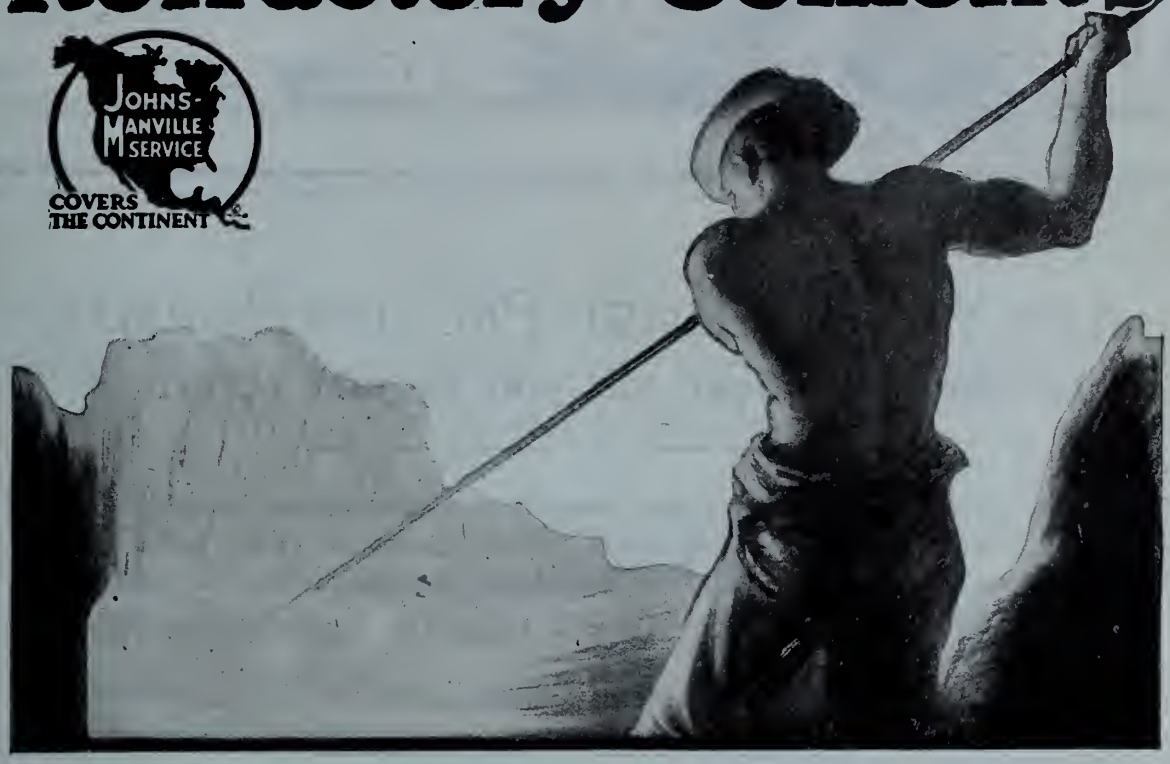
JOHNS-MANVILLE Refractory Cements



—The Modern Binder for the Modern Boiler Setting

BECAUSE a thing has "always been done that way" is no reason for continuing the old method, especially if it's wasteful and inefficient. Today's work calls for today's methods, today's materials, today's efficiency.

For many years engineers have shut down the boiler every so often to point up or replace the setting—because they relied on fire-clay, and fire-clay failed. The continual expansion and contraction of brick-work squeezed it from the joints, and it cracked and fell out, weakening joints and permitting further destructive inroads of heat. And then came air leaks and lower furnace temperatures or perhaps a fallen arch and the inevitable costly shut-down for repairs.

Today many engineers lay up their boiler settings in Johns-Manville High Temperature Cements — No. 26 or No. 31 for the bond, and No. 32 for surface protection. By taking advantage of materials expressly designed for furnace service they save many a shut-down, for these cements lengthen the life of settings. And each shut-down saved means corresponding savings in labor, materials and heavy overhead charges against idle equipment.

Test them for yourself — set up a portion of your wall with these refractory cements and check up the results. Our nearest branch will supply particulars.

For the Small Plant, Too

Interior of a cold storage room insulated with Nonpareil Corkboard before the Portland cement plaster had been applied. L. A. Mertz Dairy, Rochester, N.Y.

Some owners of small plants conclude that the size of their installation does not warrant the use of the best materials obtainable. But unless they are buying only for the present, with no thought of the future, it is the most expensive course they can pursue.

Whether the plant is small or large, the use of

Nonpareil Corkboard Insulation
FOR ALL COLD STORAGE ROOMS

will prove to be a paying investment. This is being demonstrated every day. Just read what the Sinton Dairy Company, Colorado Springs, Colorado, wrote on April 24, 1916:

"We find the (Nonpareil) cork insulation very efficient. Of course ours is a small plant and we debated the advisability of installing such high-grade insulation; but after a year's use we feel that we have done well to use your cork. It's like buying a good motor truck instead of a cheap one—high cost at first, but cheaper and less grief in the long run."

Detailed information, telling how you can use Nonpareil Corkboard profitably in your plant, will be sent free of charge on request.

Also manufacturers of Nonpareil Cork Covering for cold pipes and tanks; Nonpareil Insulating Brick for boiler settings; Nonpareil High Pressure Covering for steam lines; Nonpareil Cork Machinery Isolation for deadening noise of fans, motors and pumps; and Linotile for floors in offices and residences.

The Sure Way

to rid boilers of scale, pitting, corrosion, foaming, etc., is to treat each case individually and scientifically—

That's the "Dearborn" Way

Dearborn Feed Water Treatment is scientifically prepared (after analysis of feed water) to meet the requirements of the mineral ingredients and other objectionable constituents of the water, the percentage of each mineral salt governing the percentage of the antidotal ingredient in the treatment. By these methods we avoid the use of an excess or deficiency of any part of the treatment, every pound being utilized in the reactions taking place. There is no mechanical, unknown or unlooked for result obtained from the use of our goods; we cause a complete chemical reaction to take place between the deleterious constituents of the water and the ingredients of our preparations.

Send us a gallon of your feed water — we will analyze it and tell you what the Dearborn Treatment can do and what the cost will be.

IT'S ONLY BUSINESS for you to investigate any proposition which promises big economies and big gains in operating efficiency.

How Advertising Protects

A CERTAIN Canadian manufacturer recently received a long distance telephone message, asking him to quote on a lot of equipment required for a certain big undertaking. He caught the first train for the city in which the inquiry originated and as a result closed an order for over $50,000!

This manufacturer took the trouble to come into our office one day this week and frankly told us of the circumstances under which the order referred to had been secured. It developed that the manufacturer in question knew absolutely nothing about the tender being out and it was solely through the appearance of a full page advertisement in our paper that he received the inquiry which resulted in the order for $50,000.

Here was a manufacturer, a keen wide-awake man, with a supposedly efficient sales organization, equipped for keeping in touch with all worth while developments. Had this manufacturer relied solely upon his sales staff he would have lost out but, as we said before, being keen and wide-awake, he had provided for just such contingencies by *advertising*.

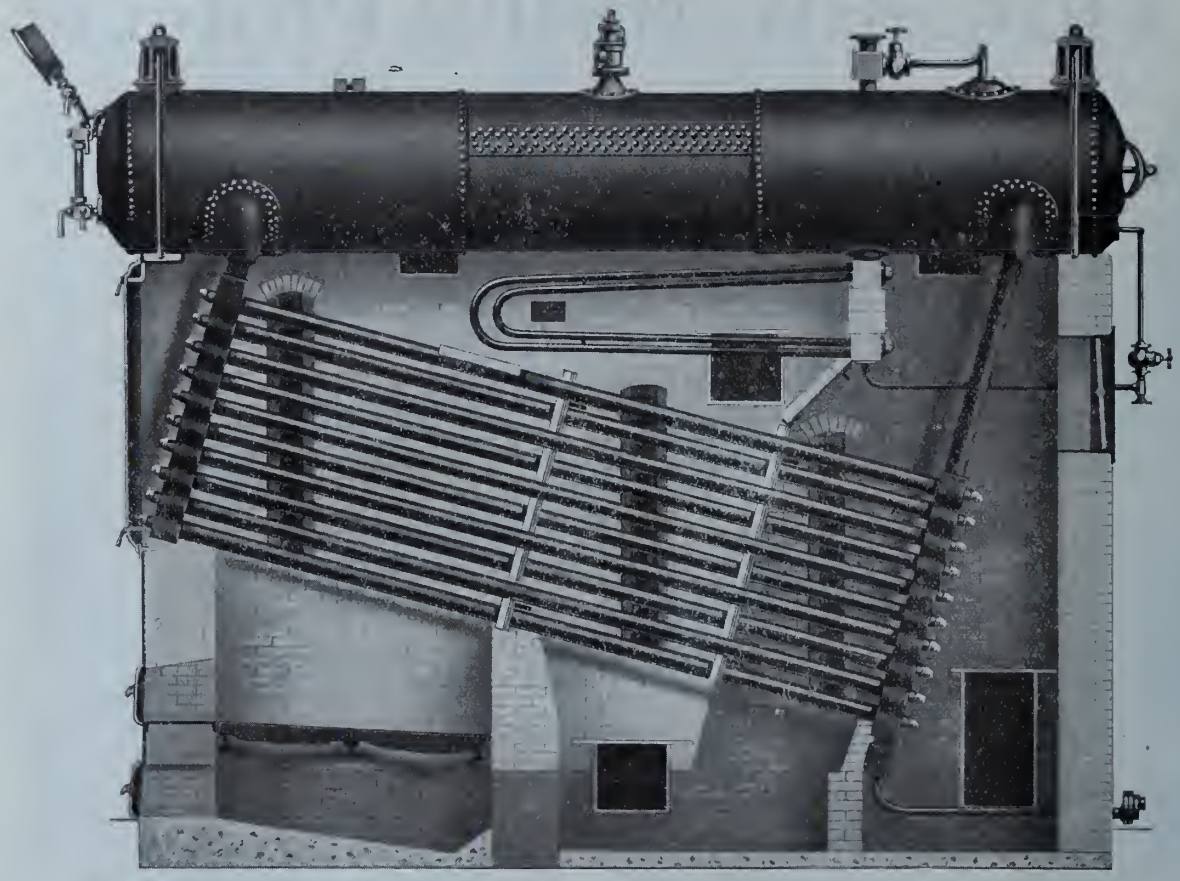
Advertising—the salesman who is everywhere at all times, who never sleeps, who is ever on guard,—proved his worth in this case just as he has shown his mettle so often before.

Even in this instance advertising might not have received the credit for the splendid results secured had not our good friend and advertiser taken the trouble to ascertain just how and why he received the inquiry which led to the order.

Naturally the manufacturer in question asked us for obvious reasons to refrain from mentioning any names at the present time, but the facts were so interesting that we felt impelled to pass them on that a consideration of them might strengthen the already unwavering conviction of those who have advertised long and believe fully in the power of advertising, and encourage those who are almost but not quite convinced that advertising is a necessary force in business. And there are still a few in this state of mind.

G. & McC. CO.

BOILERS



Sectional View, Standard Type "B," Sectional Water Tube Boiler, with Superheater.

G. & McC. Water Tube Boilers are fitted with large Steam and Water Drums, connecting nipples of increased size and straight 4" tubes, all of which insure

POSITIVE AND RAPID CIRCULATION, and INCREASED STEAMING CAPACITY

All parts subjected to steam pressure are made of FORGED STEEL

Mechanical and Electrical Equipment of a Modern Hotel

Staff Article

Increased capacity for service in its every departmental feature constitutes one of the chief developments of recent years in the design, construction and equipment of large, modern hotels, both at home and abroad. That the Royal Connaught is a front-ranker with respect not only to artistic appointment, but to the comfort and convenience of its guests will be readily apparent from a study of the mechanical and electrical installation which follows.

THE idea of building the Royal Connaught Hotel in Hamilton, originated with the Board of Trade who felt that there was a need in that city for a first-class hotel to meet the demand of tourists and commercial travellers. The aim of the originators of the scheme was to provide accommodation for the public at medium prices, while for travellers, combination sample and bedroom form a feature.

Hotel Accommodation.

The Royal Connaught is on of the finest hotels in Canada, and no expense has been spared in furnishings and in providing for the comfort of its patrons. The furnishings and decorations were designed and supplied by the T. Eaton Co., of Toronto. The management cater particularly to conventions and social functions, and for this class of business, a number of rooms have been provided having accommodation for guests ranging in number from 7 to 170, while in addition, a large ball room or convention hall forms an attractive feature. The hall is 100 feet by 65 feet and has a seating capacity of 1,000. It has a separate kitchen for use when required for banquets. The hotel has 250 rooms, 200 having bathrooms. They are all outside rooms. The hotel is operated by the Connaught Hotel Co., which is one of the United Hotels Co.'s chain of hotels. It is under the personal management of Geo. H. O'Neil, who is also proprietor of the Tecumseh Hotel, London, Ont. Dudley R. Laver is the chief engineer having charge of the power plant—all the entire mechanical equipment in the hotel.

The Royal Connaught Hotel is of brick and steel construction and is fireproof. The windows have steel sash, with factory wired glass in the bedrooms. The layout of the hotel is modern and a number of new features have been incorporated. Stone and Webster, of Boston, Mass., were the engineers. while Essenwein and Johnson of Buffalo, N.Y., were the architects, with the latter firm was associated A. W. Peene, of Hamilton. The Hamilton Bridge Works had the steel contract and the Yates Co., of Hamilton, the brick contract. The hotel was opened on June 5th. 1916.

Electrical Power Purchased.

The fact that electricity was obtainable at a reasonable rate from the Dominion Power and Transmission Co., of Hamilton, eliminated the necessity of installing a steam power plant. Direct current, however, was required for the elevator motors and to provide for these, motor-generators were installed. The electrical installation, however, is important and very efficient, and forms an interesting feature of the hotel. The electric motors of which there are a considerable number, operate on alternating current, with the exception of those for the elevators. A number of machines in the kitchen are operated by motors, while the machinery in the laundry is also motor driven. There are altogether 32 motors in the hotel, aggregating 356½ h.p., these include, in addition to those mentioned above, motors for the various pumps, fans and refrigerating plant. The alternating current for the motors is 3 phase, 66 cycles and 220 volts, while the direct current for the elevator motors is 250 volts. The current for the lighting system is alternating, 3 wire, 110 volts.

Plant Location

The power plant is located in the basement of the hotel, and includes a room containing the motor generator sets and ammonia compressors for the refrigerating plant. Adjacent to this room is the boiler room and the pump room. Above the pump room on a mezzanine floor is the hot water heating outfit, the drinking water filter and vapour tank for the heating system. The refrigerating room is near the boiler room and on the same level.

FRONT ELEVATION, ROYAL CONNAUGHT HOTEL.

Switchboard Feature.

It will be in order to describe the switchboard first, as all the power required for operating the plant is received here before being distributed. The switchboard and instruments were supplied by the Canadian Westinghouse Co., of Hamilton. L. K. Comstock & Co., of Montreal, were responsible for the layout of the electric end of the plant, both for the power and lighting systems. The switchboard is 15 ft. 6 ins. long by 7 ft. 3 ins. high and has six black slate panels. The first panel controls the main feeders for the lighting system and has an oil circuit breaker for 3 phase 66 cycle 220 volt current. There is also a 110-volt knife switch. This panel has a volt meter for indicating the voltage on the lighting and power mains, controlled by a voltmeter switch. The second panel is for the 100-k.w. motor generator set, which furnishes direct current, 250 volts, for the elevator motors. There are on this panel two triple pole, 500 ampere, knife switches, a circuit breaker, an a.c. ammeter and a field rheostat. The third panel controls the 50-k.w. motor generator set. It has two triple-pole, 400-ampere, knife switches, a field rheostat, a circuit breaker, one a.c. voltmeter for getting voltage on either generator or bus, and an ammeter.

The fourth is the power feed panel, and controls the a.c. motors in the hotel. There are two 50-ampere triple-pole switches for the fans and kitchen motors; two 200-ampere triple-pole switches for pump and laundry motors; two 60-ampere, double-pole, switches, feeding the battery charger and garage elevator motor; two 400-ampere, double-pole, switches feeding the freight, service and passenger elevator motors. The fifth panel controls the lighting feeders to various distributing boards in the hotel. This panel has the following switches:—One 200-ampere, triple-pole switch for east wing switchboard and a similar switch for the north wing. One 100-ampere, double-pole, knife switch for the garage, one 200-ampere, double-pole switch for the laundry and another for the boiler and pump room. The sixth is an extra power panel feeding the fans for the ventilating system. It has one 200-ampere, triple-pole switch for the fans and a 60-ampere switch for a pump. There is a clock on the board which is connected to the clock system.

Motor Generators.

Two motor generator units are installed for supplying direct current for the elevator motors. Both were supplied

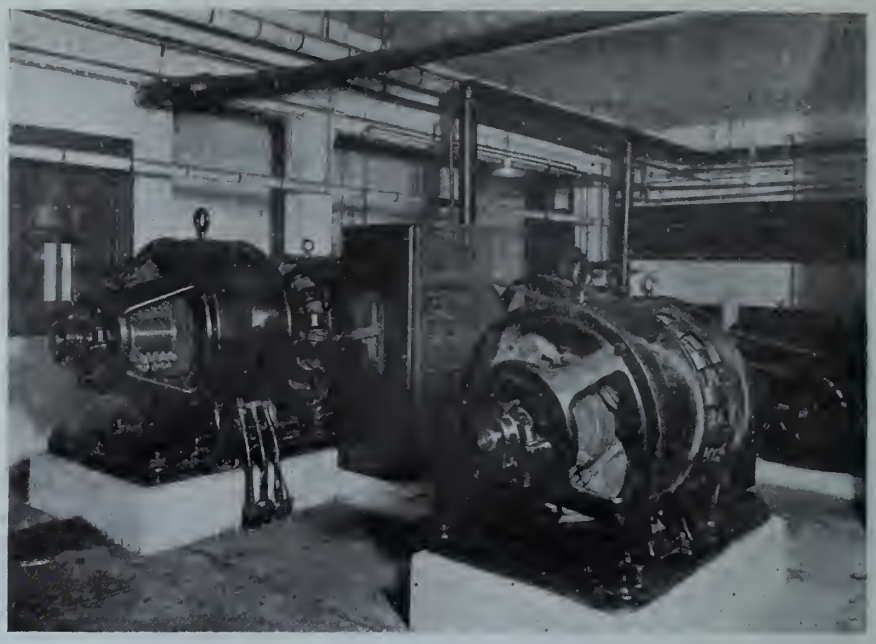
by the Canadian Westinghouse Co. The largest is a 100-k.w. 250-volts, 400-ampere machine, and runs at 970 r.p.m. The motor is 150 h.p., 220 volts, 66 cycle, 3 phase. The generator is 4 pole, compound wound with interpoles. This unit has a Westinghouse type Q auto starter, with overload release.

The second unit has a 50-k.w., 250-volt, 220-ampere generator, with 75-h.p. motor, 220 volts, 202 ampere and runs at 970 r.p.m. This unit has a Westinghouse-type K auto starter.

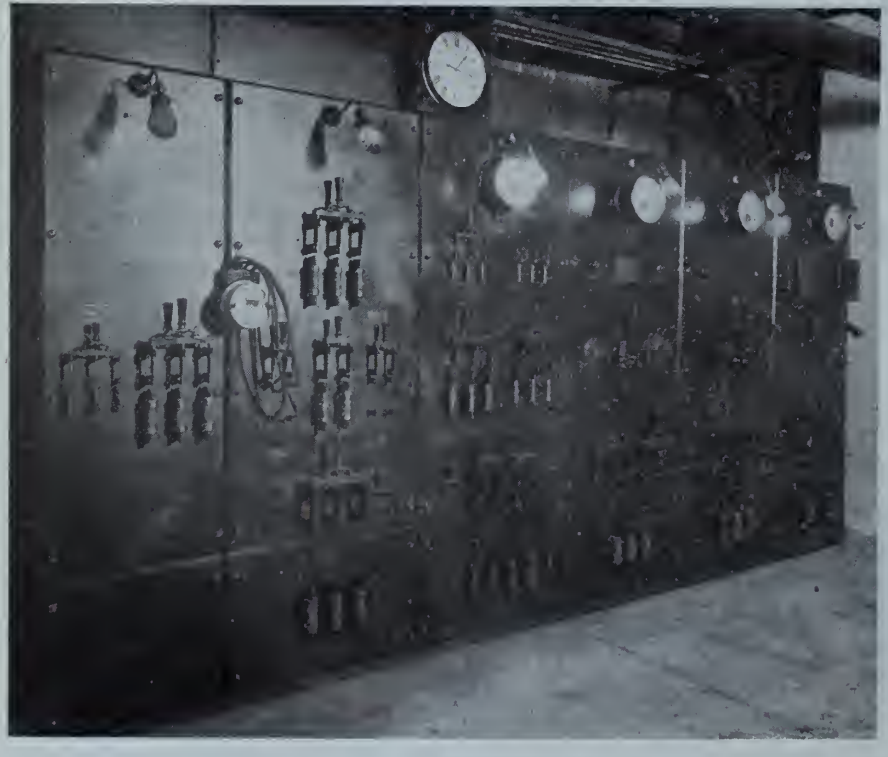
Refrigeration Plant.

The ammonia compressors are located in the same room as the motor generators. They are used in connection with the ice-making plant and the cold-storage system. The refrigeration plant was supplied and installed by the Canadian Ice Machine Co., Toronto. The two compressors are "York" vertical, enclosed machines and have a capacity of 12 and 8 tons respectively. The former has a cylinder 7½ in. diam. by 7½ in. stroke, while the latter is 6½ in. diam. by 6½ in. stroke. The 12-ton machine is belt driven by a 20-h.p. Can. Westinghouse a.c. motor, 220 volts, running at 850 r.p.m. The 8-ton machine is driven by a 15-h.p. a.c. motor, also running at 850 r.p.m. The ammonia condenser installation is situated near the compressors and consists of two double-pipe condensers. 8 pipes high, 19 feet long and made of 1¼-in. and 2-in. pipe. The ammonia receiver is 20-in. diameter by 7-ft. long and the oil trap is 8 in. diam. by 48-in. long. The gauge board has the following: One high-pressure gauge and vacuum gauge, one suction-pressure and vacuum gauge, one water-pressure gauge and one brine gauge.

The combined brine and ice-making tank has a capacity of two tons of ice daily. The tank is 18 feet long, 10 feet wide and 4 feet deep and is insulated with 6-in. of nonpareil sheet cork on bottom and sides. The tank has three double-pipe brine coolers, six pipes high by 16 feet long, made of 2-in. and 3-in. pipe. This is used as a cooling medium for the calcium brine contained in the tank, which is held at approximately 10 to 14 degrees Fahr. The tank also contains 54—8-in. x 16-in. x 32-in. galvanized iron ice cans, each capable of producing a block of ice weighing 100 lbs. Filtered water is used when filling the cans. The same filter is used for purifying the drinking water.



"CANADIAN WESTINGHOUSE" MOTOR-GENERATORS SUPPLYING DIRECT CURRENT TO ELEVATOR MOTORS.



MAIN SWITCHBOARD LOCATED IN MOTOR-GENERATOR ROOM.

There are nineteen refrigerators in the hotel, located principally in the vicinity of the kitchen used for keeping perishable and cooked food, ice storage and garbage, etc. These refrigerators vary in size, the largest being 43 ft. 6 in. long by 7 ft. wide by 8 ft. high, and containing 1,160 ft. of piping. The majority of these rooms are held at a temperature ranging from 32 to 36 degrees, the principal exception being the ice-cream box, which has a temperature of 5 degrees. These refrigerators are fitted with 1¼-in. brine coils, the total amount of piping being 2,600 feet. The brine is pumped from the ice tank through the coils by a Smart-Turner centrifugal pump, having a capacity of 100 gallons per minute and direct connected to a 7½-h.p., a.c. motor, Canadian Westinghouse make running at 1,700 r.p.m. The Canadian Ice Machine Co. supplied the coils and the refrigerators were furnished by the Canadian Jewett Refrigerator Co. A motor-driven ice crusher supplied by the Allman Gas Engine Co., New York, and a motor-driven cube ice cutter, built by G. S. Blakeslee & Co., of Sarnia, Ont., are installed near the brine tank.

The drinking water for the hotel is filtered and cooled, the apparatus for this purpose being situated on the mezzanine floor over the pump room. The water is first passed through a York charcoal filter, 18 in. diam. by 24 in. deep. It then flows to a galvanized steel tank, 5 ft. diameter by 5 ft. 6 in. deep, which contains 460 feet of 1¼-in. galvanized direct expansion coils for cooling water to 40 degrees. The water is pumped to a tank at the top of the building, from where it circulates to the drinking-water faucets. The pump is Smart-Turner make, and it has a capacity of 38 gallons per minute. It is direct connected to a 5-h.p. Can. Westinghouse motor running at 1,700 r.p.m.

The water for filling the cans, after passing through the charcoal filter, men-

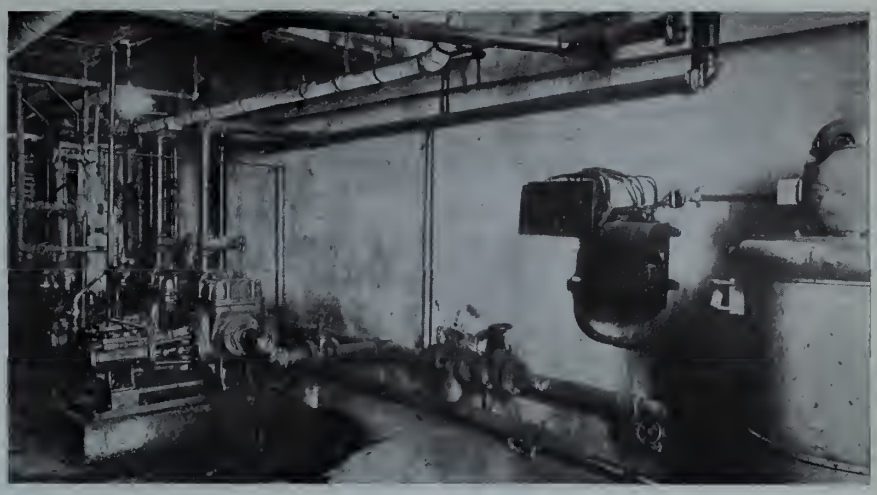
tioned above, goes to a galvanized steel tank 4 ft. diam. by 4 ft. 6 in. deep, which contains 100 ft. of 1¼-in. galvanized direct expansion coils. This water is cooled before going to the cans, so that the temperature of the brine in the ice tank will not be materially affected, as it would be otherwise.

Heating and Ventilating.

At the present time, the Dominion Power Transmission Co. are supplying steam to the hotel under contract, for heating and also for the laundry and kitchen, etc. The reason for this arrangement is that the power company, whose plant is quite near the hotel, can supply steam at a low rate, owing to the fact that they have an ample supply available all the year round. Under prevailing conditions, considerable economy can be effected by this arrangement. The hotel, however, has an independent heating plant for use in case of emergency.

The steam from the Dominion Power Co.'s plant comes in at a pressure of 80 lbs. through a 6-in. main, which connects with the hotel system in the boiler room, where is installed a General Electric Co.'s type M recording steam flow meter for registering the amount of steam taken from the incoming main. A ¾-in. American trap is installed in this line to take care of the drains.

The emergency boiler was built and supplied by the Goldie & McCulloch Co., of Galt, Ont. It is of the water-tube, single-drum type, 125 h.p. It is built for a working pressure of 165 lbs. per sq. in., but is only operated, when in use, at 80-lbs. pressure. There are two Foster reducing valves installed in the system, one for reducing the high pressure steam down to 40 lbs. for the kitchen, and the other for the heating system, which uses steam at about 3-lbs. pressure. The steam in the line to the laundry is at boiler pressure, 80 lbs. Steel piping is installed throughout for the high-pressure steam lines. The valves are mostly of Jenkin Bros.' make.



VACUUM AND BOILER FEED PUMPS. "TUEC" VACUUM CLEANER AT RIGHT.

The high-pressure steam lines are covered with magnesia pipe covering, and the low-pressure steam with cellular covering.

The hotel is heated by means of radiators, fitted with Dunham traps and Canadian Detroit Lubricator Co.'s packless valves. Two Bawden vacuum pumps are installed in the pump room for taking care of the returns from the heating system. Further reference will be made to these pumps later on. The vapor tank for the vacuum pumps is located on the mezzanine floor above the pump room.

The gauges for the steam distribution system are mounted on a board in the motor generator room. The gauges were supplied by Schaeffer & Budenberg, of New York, and comprise the following: One steam-pressure recorder on high-pressure line, one laundry steam-pressure gauge, one gauge for the steam line to kitchen, one gauge for the heating system pressure and one to show the vacuum in the return main. There is one gauge for the vacuum cleaner and one to show the city water pressure.

The distribution system for the heating, hot and cold water, etc., is an interesting one. All piping is carried up an air shaft, inside the building, to a plumbing loft above the eleventh or top floor. The distributing pipes are returned down sixteen smaller shafts from which connections are made to the various rooms, etc. The chimney from the boiler is also carried up the big air shaft.

The ventilating system comprises four motor-driven fans, supplied by Sheldon's Ltd., Galt, Ont, The main ventilating fan is located in a pent house on the roof. It is a double fan, one exhausting from the kitchen and the other from the main air shaft through which the piping referred to above is carried. Connections are made from the corridors with this air shaft. The foul air from the kitchen is carried up to the fan through a galvanized iron duct run up the wall outside the building. This fan is driven by a 20-h.p. Can. Westinghouse a.c. motor running at 1,245 r.p.m. There is another exhaust fan in a pent house on the roof for ventilating the lavatories and bathrooms. This fan exhausts from the plumbing loft, connection being made to the lavatories, etc., by means of the sixteen air shafts. This fan is driven by a 7-h.p., a.c. motor at 1,245 r.p.m.

On the second floor over the hotel annex are two other fans, one for ventilating the laundry, engine and boiler room, and the other for the convention hall. The former is driven by a 7½-h.p. motor running at 1,245 r.p.m., while the latter is driven by a 5-h.p. motor running at 945 r.p.m. The motors are all Canadian Westinghouse make.

8 AND 12-TON "YORK" AMMONIA COMPRESSORS.

Pumping Installation.

This installation comprises the boiler-feed pumps, vacuum pumps, booster pump for cold-water service and stirrup pumps. There are two pumps for the boiler, both being the same make and size. They are duplex horizontal, 5¼ x 3½ x 5 in. Smart-Turner pumps. There are two vacuum pumps, both supplied by the Bawden Pump Co., Toronto. These are horizontal pumps, 6 x 3 x 10 in. and draw the returns from the heating system and deliver to the receiver. The

pumps are controlled by a Fisher governor. This receiver collects all the returns from the various steam lines. The returns from the kitchen are taken care of by a ½-in. Anderson trap and those from the laundry by a 1¼-in. Anderson trap. There is a sump under the pump room floor for collecting seepage and drips from the pumps, etc. In the sump is a 150 gal. Smart-Turner centrifugal pump driven by a 1-h.p. motor running at 1,245 r.p.m. and controlled by a Hamilton Motor Works float switch.

The hotel water supply enters the building in the pump room. It comes in from the city main through a 4-in. pipe and passes through a "Trident" meter up to a tank on the roof. As a precaution against the city pressure dropping, a booster pump is installed. This unit is a 2-in. Kerr vortex turbine pump driven by a 7½-h.p. Crocker-Wheeler a.c. motor running at 1,720 r.p.m. The pump is equipped with a "Sundh" auto-starter working in conjunction with a float in the tank on the roof. In the basement are two sewage pumps, located in a sump, which collects the effluent from the basement lavatories and other drains. They are both Smart-Turner centrifugal pumps, having a capacity of 100 g.p.m., each driven by a 2-h.p. motor operating at 940 r.p.m., and controlled by a "Sundh" float switch.

INTERIOR OF HOTEL LAUNDRY.

The plant for providing hot water is situated on the mezzanine pump floor. The water in the storage tank is heated by two Alberger heaters using low-pressure steam. The temperature of the water is controlled by a No. 11 tank regulator, self-contained type, supplied by the Canadian Powers Regulator Co., Toronto. The hot water is held at a temperature of 160 degrees Fah.

Elevator Installation.

The elevators were built and installed by the Otis Fenson Elevator Co., and comprise two passenger, one service, and one freight elevators. There is also an elevator in the garage at the back of the hotel. This elevator, while not part of the hotel installation, is operated by power from that plant.

The two passenger elevators are single-screw, worm-gear, traction type, having a capacity of 2,500 lbs. They have a speed of 300 ft. per minute, with a load of 2,000 lbs. The cars are 6 ft. by 6 ft., and they have a travel of 126 ft. These elevators are equipped with flash-light annunciators and electric interlocks, which prevent cars starting when the doors are open.

The service elevator has a maximum capacity of 2,500 lbs. and a speed of 200 ft. per minute, with a load of 2,000 lbs. The car is 6 ft. by 6 ft. and travels 139 ft. 6 ins.

The freight elevator has a capacity of 3,000 lbs. and a speed of 150 ft. per minute. This elevator has a travel of 39 ft. 11 ins. and the car is 6 ft. by 8 ft. The machines are located overhead in all cases.

The garage elevator is a special single belt, worm-gear type, having a capacity of 3,500 lbs. and a speed of 40 ft. per minute. The car is 8 ft. by 16 ft. and has a travel of 9 ft. 6 in. The elevator in all cases is operated on 250-volt, a.c. current from the motor generators in the hotel basement.

Lighting System.

The lighting is a 110-volt, 3-wire, a.c. system, and was installed by L. K. Comstock, of Montreal. The wiring is carried from the main switchboard to the distributing wall boards situated in the basement which control various sections of the hotel. On each floor, there are two enclosed wall panels having fuses for various circuits and controlled from the above-mentioned basement switchboards. All these switchboards and fuse panels. etc., were supplied by the Canadian Krantz Co., Toronto. All the wiring is run in galvanized conduit.

Laundry.

A laundry is operated for the benefit of the hotel guests only, and a seven-hour service is maintained. All the equipment was supplied by the Canadian Laundry Machinery Co., Toronto, and consists of the following:—Three brass-cylinder, 125 shirt washers, one tumbler, two 28-in. hydro-extractors, one dry tumbler, one "Hurricane" steam-heated dry room, one steam-heated body ironer, one 30-in. collar machine, three complete electric ironing boards, one electric collar molder, one gravity seam dampener, one four-roll, extra flatwash ironer, American type, one starching tub, one "Uneeda" collar starcher, one steam bosom board and a full line of press machines. The line shaft is operated by a 10-h.p. Can. Westinghouse motor, while some of the machines are motor driven.

Kitchen Motors.

The kitchen is spacious and the equipment is up-to-date in every respect. The kitchen is situated in the basement and adjoining it are the store rooms, pantries and staff mess rooms, etc. In connection with the kitchen equipment, it may be of interest to give the sizes of motors for the various machines, these are as follows: Knife cleaning machines, 1-3 h.p.; dish washer, ¾ h.p.; ice-cream freezer, 2 h.p.; potato peelers, ¼ h.p.; meat chopper, 1 h.p., and coffee grinders, ¼ h.p. These are all a.c. motors and of various makes.

Miscellaneous Features.

An efficient fire protection system is installed in the hotel. Two stand pipes running up to the top of the building are connected to the city mains and also to the water tank on the roof, the latter being an emergency arrangement. There are hose connections on each floor and in addition, there are hand fire extinguishers.

A watchman's clock system is installed, with stations on each floor, making a total of 26. There is a recording apparatus in the hotel office connected to the stations.

A time clock system is also installed, being supplied by E. Howard & Co., Boston, Mass. A master clock on the mezzanine floor near the private office controls thirty clocks located in various sections of the hotel. The system is operated from storage batteries.

The machine for the vacuum cleaning system is installed in the pump room. It is a 6-sweeper "Tuec" unit and handles 1,200 cub. ft. of air per minute. Operation is by a 10 horse-power a.c. motor. The outlets are located at different points on each floor, so that a maximum length of 50 feet of hose can reach all parts of the building. The hose is 1¾ in., and the tools are specially designed to give most efficient cleaning. The risers are all 2½-in. pipe, giving thereby free passage and eliminating all tendency to clogging up.

The horsepower of an engine may be increased within the working capacity of the reciprocating parts by increasing the speed or by increasing the steam pressure.

Test Data Relative to Uniflow Steam Traction Engines*

By F. W. Marquis

This paper presents the results of two series of tests of Baker uniflow steam traction engines, many of them being shown graphically in the form of curves. The steam consumption of these engines is compared with those representative of the older or counterflow type of prime movers, and the conclusion is reached that the simple uniflow engine operating non-condensing with saturated steam has a lower steam consumption than the compound counterflow engine under like conditions and that, when operating non-condensing but with superheated steam, it will have approximately the same steam consumption as a compound counterflow engine when condensing and using saturated steam.

AT FIRST thought it seems strange to find refinements such as the uniflow cylinder and the superheater in connection with traction engines; but when it is remembered that the latter are used extensively in certain districts where fuel is very expensive, and water has to be hauled many miles, the reason for taking advantage of every means for reducing coal and water consumption becomes readily apparent.

Efficiency tests covering uniflow steam traction engines made by the A. D. Baker Co., Swanton, Ohio, have been carried out on two occasions, the first during the year 1915, and the second during 1916. The engine tested in the latter year was almost identical with that tested during 1915, the exceptions being that the 1916 boiler was supplied with a smokebox type of superheater, and its water heating surface was 24½ per cent. greater; in addition the 1916 engine piston displacement showed an increase of 8½ per cent. Both engines were of the makers' standard designs except for the uniflow cylinder and superheater, which were then in process of development. The principal dimensions of both engines are given in Table 1, and besides the uniflow cylinder and the superheater, a feature of particular interest is that of the valve gear, a description of same being included.

Figs. 1 and 2 show cross sections through the uniflow cylinder and valves. As well as triple ported admission valves there is an auxiliary exhaust valve which causes the point of compression to come late in the stroke, instead of at the point where the piston covers the main exhaust ports as is the case with uniflow engines not provided with some form of auxiliary exhaust valve.

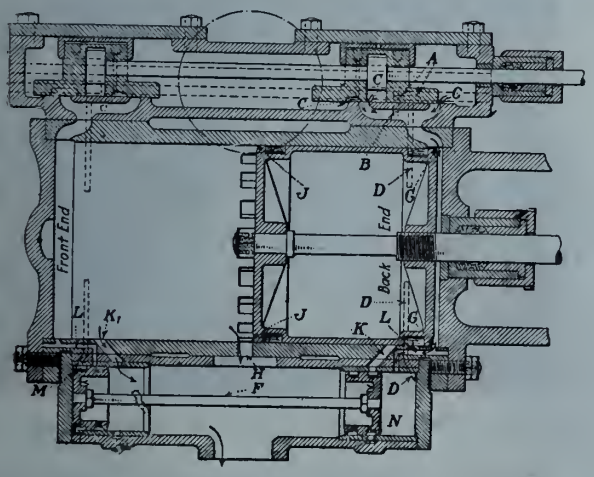


FIG. 1. BAKER UNIFLOW CYLINDER AND VALVES.

	Engine used in 1915	Engine used in 1916
ENGINE		
Nominal horsepower	16	18
Nominal r.p.m.	240	240
	In.	In.
Diameter of cylinder	8¾	9¼
Stroke	10½	10
Diameter of piston rod	1¼	1½
Diameter of flywheel	36	38
Face of flywheel	10	11
Diameter of cranksbaft	3	3½
Length of cranksbaft	55½	61½
Diameter of crankpin	2½	2½
BOILER		
Number of tubes	40	54
	In.	In.
Outside diameter of barrel	29	32

Tube heating surface	123 2	153.6
Total water beating surface	146.8	182.7
Superheater heating surface		47

TABLE 1. PRINCIPAL DIMENSIONS OF BAKER UNIFLOW TRACTION ENGINES.

Valve Operation

The operation of the valves can best be explained by following their movement as the piston moves through one stroke. Suppose the piston to be moving towards the right and nearing the end of its stroke; that is, that it is just a little to the left of its position in Fig. 1. The admission valves (at the top) will then be a little to the right of the position shown, and moving towards the left. The auxiliary exhaust valve F (at the bottom of the figure) will be at the extreme right end of its travel, and stationary.

When the edge J of the piston uncovers the ports at the centre of the cylinder, exhaust commences. About the same time the cavity A in the admission valve uncovers the port at the end of passage B and allows live steam to flow from E (see Fig. 2), through passage B, cavity A and passage D into chamber N at the end of auxiliary exhaust valve F. This causes valve F to move to the extreme left of its travel, closing the auxiliary exhaust port K and opening the auxiliary exhaust port K^1. Exhaust is then taking place both through the main exhaust ports and through exhaust port K^1. An instant after the auxiliary exhaust valve moves and just before the piston reaches the end of its stroke, admission takes place through the three ports C.

As the piston starts on the return stroke towards the left, exhaust takes place through the main exhaust ports at the centre of the cylinder until, early in the return stroke, they are covered by the piston. The steam still in the cylinder continues to exhaust through auxiliary exhaust port K^1, until the piston covers this port, late in the stroke, when compression starts. Meanwhile live steam has been admitted on the other side of the piston until the admission valve has returned and cut-off has occurred. After cut-off and during expansion, the live steam in chamber N, at the head of the auxiliary exhaust valve, is free to expand through passage L and do work on the piston. This passage L enters the auxiliary exhaust valve chamber at such a point that when the valve is thrown some steam is trapped between it and the end of the valve chamber, thus cushioning it and preventing pounding.

The admission valves are driven by a Baker valve gear, which is very similar to the Baker gear now being used extensively in locomotive practice. It is a

*From a paper read before the American Society of Mechanical Engineers.

single-eccentric variable cut-off and reversing gear which maintains equal leads for all cut-offs and in both directions of running. It consists of an eccentric arm A (Fig. 3), connected at one end to the eccentric and at the other end

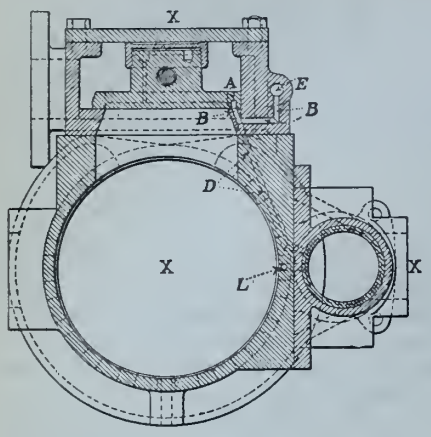

FIG. 2. BAKER UNIFLOW CYLINDER AND VALVES.

to the lower end of radius arm B. This radius arm is supported at the top by a pin C which can be held in place at any point on the arc shown in Fig. 3 by a reverse yoke. The eccentric arm A is connected to the bell crank E by means of the connecting rod F. The valve rod H is attached to the bottom of the bell-crank arm. The eccentric is set exactly 90 degs. ahead of the crank.

When the engine revolves, the eccentric moves one end of the eccentric arm in a circle, and the other end is caused to swing in an arc by the radius arm B. The motion of point P (the point at which the connecting rod F is attached) is then a combination of these two motions. The horizontal arm of bell crank E will then be moved up and down and the vertical arm back and forth, thus driving the valve rod.

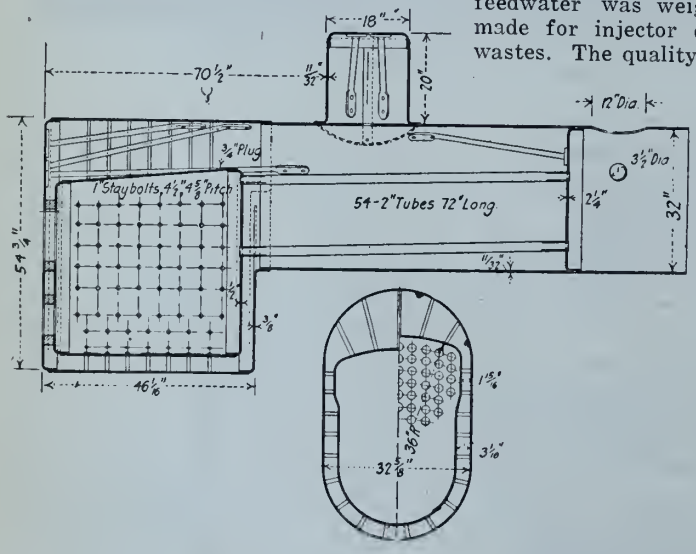

FIG. 4. BOILER OF TRACTION ENGINE.

The point of cut-off is changed and the engine reversed by moving the reverse yoke and thus changing the position of pin C, about which the radius arm B revolves. When the engine is on centre, the end of the eccentric arm and the point of support of the reverse yoke are exactly in line, so there is no motion of the eccentric arm (and valve) when the reverse yoke is moved (engine still on centre). Thus the lead remains constant for all positions of the reverse yoke, i.e., for all cut-offs.

Boiler and Superheater

In Fig. 4 is a drawing of the boiler used in the 1916 tests. It is almost identical with that used in 1915 except that it is a little larger, having 24½ per cent. more heating surface.

In 1916, a superheater was placed in the smoke box. It is shown in place in Fig. 5, and removed in Fig. 6. It consists of a vertical cast-iron header into which tubes are inserted, as shown in Fig. 6. Steam enters through pipe A, Fig. 7, which leads from the steam dome and passes to the front section of the header. It then passes back through the ½-in. pipes and forward through the 1½-in. pipes into the back section of the header. Thence it passes through pipe B to the steam chest.

Test Procedure

The tests were conducted in the Me-

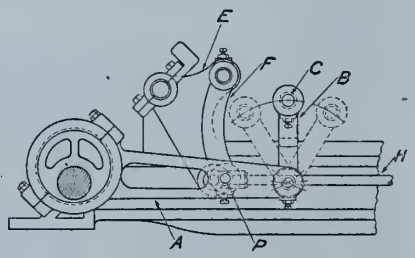

FIG. 3. BAKER VALVE GEAR.

chanical Engineering Laboratory of the Ohio State University and in general the methods recommended in the A.S.M.E. Power Test Code were followed. All coal fired was weighed, sampled, analyzed and the calorific value determined. The feedwater was weighed and correction made for injector overflow and other wastes. The quality of steam was taken

FIG. 5. SUPERHEATER IN PLACE IN SMOKEBOX OF BOILER.

by means of a Barrus throttling calorimeter, the sampling pipe being located in the path of the steam as it left the steam dome. Smokebox temperatures were determined by means of a thermocouple and the smokebox gases were sampled continuously and analyzed by means of an Orsat apparatus. Indicated and brake horsepower and revolutions per minute were all carefully determined. All instruments were calibrated and corrections applied where necessary.

The tests were run with the throttle valve wide open, and except where otherwise noted it was attempted to maintain the speed constant at 250 r.p.m. During the preliminary running preceding each test, the brake load was adjusted so that the desired speed was obtained when the throttle valve was wide open. During each run all conditions were maintained as constant as possible.

Programme of Tests

First Series.—The 1915 series consisted of 17 tests with various boiler pressures ranging from 125 lbs. gauge to 175 lbs. gauge, and various cut-offs ranging from 6 per cent. to 49 per cent. of the stroke. Saturated steam was used throughout this series, and the approximate speed was 250 r.p.m. in all tests.

Second Series.—The 1916 series consisted of 17 tests, 13 at 180 lbs. gauge and 4 at 160 lbs. gauge. Nine of the former were with superheated steam, and four with saturated steam. Superheated steam was used for the four latter tests The cut-off in this series varied from 16 per cent. to 75 per cent. of the stroke. The approximate speed was 240 r.p.m., with the exception of three short runs which were made with variable speed to secure data concerning the relation between speed and power.

Results

A summary of the results having to do with engine performance is given in Table 2, and in Table 3 will be found a summary of results having to do with the boiler, and with the overall performance. Many of these results are also presented graphically in Figs. 9, 10, and 11.

In Fig. 8 are two sample sets of indicator diagrams, one with a rather early and the other with a much later cut-off. They show a remarkable lack of wire-drawing during admission, and sharp cut-off for a slide-valve engine running at such a high speed (250 r.p.m.). The drop in the early part of the expansion line of the diagrams with an early cut-off,

and that in the admission line of the diagrams with the later cut-off, is caused by the steam flowing into the auxiliary exhaust-valve chamber, at the instant the piston uncovers the port leading to this chamber.

The curves in Fig. 9 show the relation between steam consumption in pounds per i. hp-hr. and i.hp. for both the series of 1915 and the series of 1916, under the different conditions of running. Reference to this figure shows that the highest steam consumption obtained was just under 29 lbs., which occurred at 125 lbs. boiler pressure with saturated steam and at approximately 60 i.hp. The lowest steam consumption obtained in any single test was 18.2 lbs. per i. hp-hr., in the series of 1916, with 180 lbs. boiler pressure and 118 degs. superheat, at about 72 i.hp. Reference to the curve shows, however, that this point was abnormally low, the lowest point on the curve being 19.1 lbs. per i.hp. per hour.

The total range of steam consumption, from the most unfavorable conditions of high overload and low boiler pressure (125 lbs.) with saturated steam, to the most favorable conditions of economical load and high boiler pressure (180 lbs.) with superheated steam, was only from 29 to 19 lbs., or 10 lbs.

It will be noticed that at each boiler pressure tests were run with cut-offs considerably later than the most economical. It seems reasonable to assume that the engine should be rated at approximately the point of best economy. On this basis the rating when operating under 125 lbs. boiler pressure would be 45 hp. Tests were run from about 30 to about 60 i.hp. or from about 60 per cent. to 130 per cent. of this rated load, and over this range the variation in steam consumption was from approximately 29 to 26½, or only about 2½ lbs.

If the same reasoning is followed in connection with the tests run at 180 lbs. boiler pressure and with superheated steam, it will be found that tests were run over a range of from approximately 55 per cent. to 145 per cent. of full load, and that the maximum difference in steam consumption over this rather wide range was only from approximately 20½ to 23½ lbs. ,or 3 lbs.

It is interesting to note that the maximum power obtained was 108.7 i.hp. (102.8 b.hp.), which was obtained with 180 lbs. boiler pressure and with 181 degs. Fahr. superheat, and with a steam consumption of only 23.5 lbs. per i.hp. per hour (24.5 lbs. per b.hp. per hour). This becomes particularly interesting when it is remembered that the cylinder diameter and stroke of this engine were only 9¼ in. and 10 in. respectively.

The curves in Fig. 10 show the relation between steam consumption and

Column 1: Laboratory Symbol. The first term represents the number of run; the second the approximate boiler pressure and the last the position of the reverse lever upon its quadrant expressed in notches from the center back.

Column 12: Efficiency ratio, based on i.hp. This is the ratio between the thermal efficiency of the engine and the thermal efficiency of a perfect engine operating on the Rankine complete expansion cycle. It is equal to $2545/WH$, where W = actual wt. of steam per i.hp-hr., and H = the adiabatic heat drop from pressure and quality of steam furnished to engine to exhaust pressure.

[1] Valve setting changed between runs No. 8 and No. 9.

[2] Runs No. 10, No. 11, and No. 12 are short variable-speed runs. Run No. 13 is a short maximum-power run.

boiler pressure. As the boiler pressure increases, not only does the steam consumption decrease, but also the power at any cut-off, and the power at which

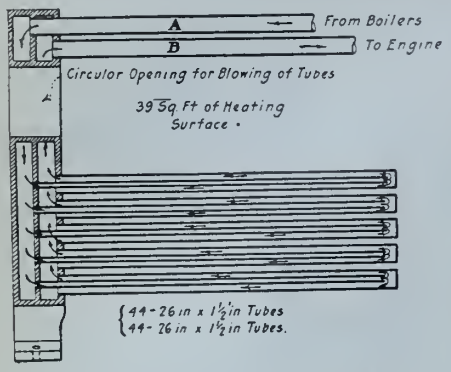

FIG. 7. DIAGRAM OF SUPERHEATER.

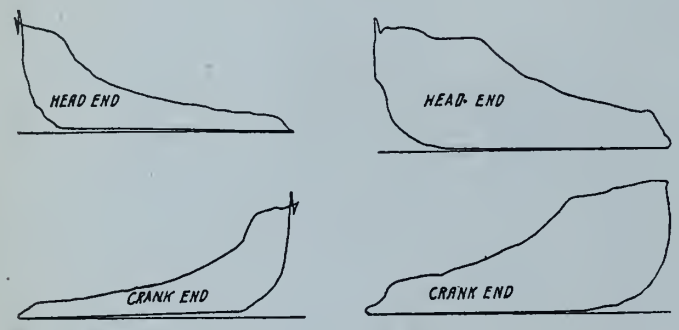
the lowest steam consumption occurs in-increases. Curve A shows the decrease in steam consumption with increase of boiler pressure at 50 i.hp., and curve B at 60 i.hp. Curve C shows the relation between the minimum steam consumption at each boiler pressure, and the boiler pressure. The power corresponding to minimum steam consumption at



Run No.1. Series of 1915. 125 lb. Boiler Pressure, Saturated Steam.

Run No.7. Series of 1916. 180 lb. Boiler Pressure, Superheated Steam.

FIG. 8. SAMPLES OF INDICATOR DIAGRAMS.

each pressure is shown by the figure near each point through which this curve is drawn. It will be noticed that, with the exception of one point on this curve, the power of minimum steam consumption increases as the boiler pressure increases.

Curve A shows that at 50 hp. the steam consumption decreases from 29 at 125 lbs. to 23.4 lbs. at 175 lbs. pressure, while curve C shows that, if the point of minimum steam consumption at each boiler pressure is taken, the decrease is only from 26.4 lbs. at 125 lbs. pressure to 23.3 lbs. at 175 lbs. pressure.

The curves of Fig. 11 show the relation between the pounds of coal used per brake horsepower per hour and the brake horsepower developed. These curves are naturally of the same general shape as those given in Fig. 9, showing the relation between steam consumption and indicated horsepower. The inconsistency in results shown by the fact that many points are not located on the curves is caused largely by the facts that it was not possible to maintain uniform conditions of combustion during the different tests, and that it was very difficult to keep the condition of the fuel bed such that there would be the same amount of coal on the grates at the end as at the beginning of a run.

It will be noted that the highest coal consumption was 5.1 lbs. per b.hp-hr., and that this occurred at 140 lbs. boiler pressure and 61 b.h.p., while the lowest coal consumption obtained in any single test was 2.98 lbs. per b.hp-hr., which occurred at 180 lbs. boiler pressure, 118 degs. Fahr. superheat, and 68 b.hp. However, this seems to be an abnormally low value, the lowest point on any curve being 3.27 lbs., corresponding to 180 lbs. boiler pressure with superheated steam and at 67.5 b.hp.

As a matter of interest from a comparative point of view, the steam consumption curves of a number of the ordinary counterflow type of steam engines, both simple and compound, non-condensing and condensing, have been plotted on the same sheet with certain of the steam-consumption curves of the Baker uniflow engine. These curves are given in Fig. 12. Information concerning each of the engines whose steam-consumption curve is given in this figure will be found below:—

Curve A.—Simple, slide-valve engine, cylinder 8 in. by 12 in., initial steam pressure 130 lbs. gauge, non-condensing, and at 200 r.p.m.

Curve B.—Simple, slide-valve engine, cylinder 9 in. by 12 in., initial steam pressure 140 lbs. gauge, non-condensing, and at 290 r.p.m.

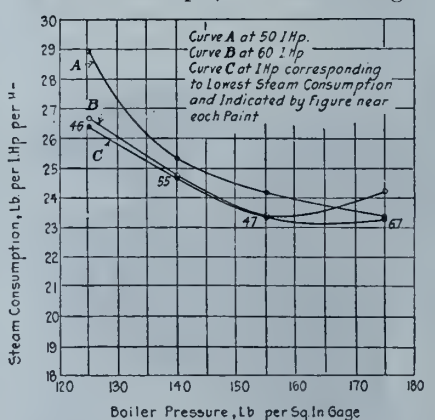


FIG. 10. CURVES SHOWING RELATION BETWEEN STEAM CONSUMPTION AND BOILER PRESSURE, SERIES OF 1915.

Curve C.—Simple, slide-valve engine, cylinder 15 in. by 14 in., initial steam pressure 115 lbs. gauge, non-condensing, and at 225 r.p.m.

Curve D.—Same engine as in case of Curve C, but operating condensing.

Curve E.—Cross-compound, slide-valve engine, cylinders 7 in. and 13 in. by 10 in., initial steam pressure 150 lbs. gauge, non-condensing, and at 310 r.p.m.

Curve F.—Same engine as in case of curve E, but operating condensing.

Curve H.—Tandem-compound, slide-valve engine, cylinders 8¼ in. and 13¼ in. by 12 in., initial steam pressure 115 lbs. gauge, condensing, and at 280 r.p.m.

Curve G.—Simple uniflow engine, cylinder 8¾ in. by 10 ¼ in., initial steam pressure 125 lbs. gauge, non-condensing, and at 250 r.p.m.

Curve I.—Same engine as in case of curve G, but with 175 lbs. gauge boiler pressure.

FIG. 9. CURVES SHOWING RELATION BETWEEN STEAM CONSUMPTION AND INDICATED HORSE POWER.

Comparisons and Conclusions

It will be seen that the uniflow-engine curves selected are those representing the poorest and the best results obtained with saturated steam, and the best results obtained with superheated steam. A study of this set of curves (Fig. 12), shows that the poorest results obtained with the uniflow engine, namely, those of curve G, obtained with saturated steam at 125 lbs. pressure, are better than the best results obtained with any of the simple engines, even when operating condensing, and almost the same as those obtained with the compound non-condensing engine shown by curve E. The steam consumption of the uniflow engine at 175 lbs. pressure with saturated steam running non-condensing is lower than that obtained with the compound non-condensing engine at 150 lbs. pressure shown by curve E. Also the steam consumption of the uniflow engine with 180 lbs. steam pressure and 130 degs. superheat, was lower than that of the compound condensing engine with 150 lbs. steam pressure shown by curve F.

Thus it is seen that on the basis of the results of the tests reported in this paper and the information presented by Fig. 12, which is thought to represent fairly the average practice for small,

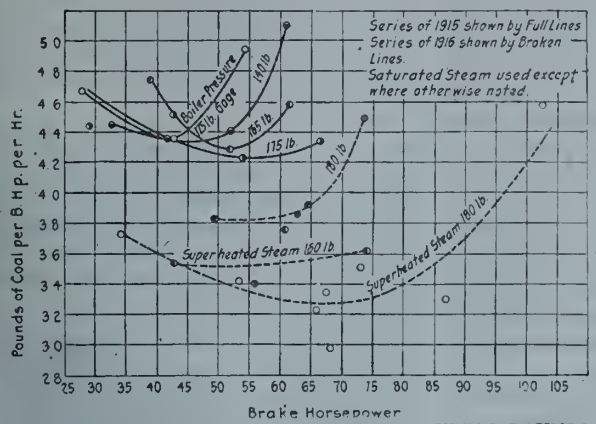

FIG. 11. CURVES SHOWING RELATION BETWEEN POUNDS OF COAL PER B.H.P. PER HOUR AND B.H.P.

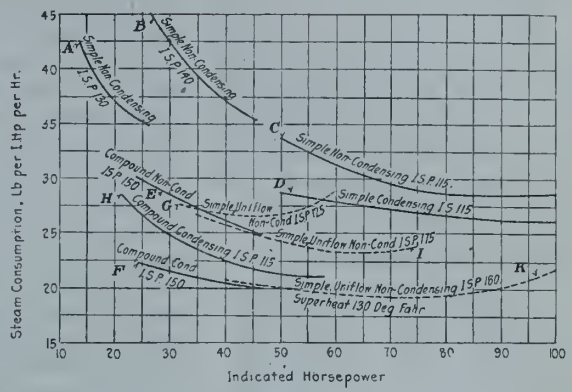

FIG. 12. RELATIVE STEAM CONSUMPTION OF BAKER UNIFLOW ENGINES AND COUNTERFLOW ENGINES.

simple and compound engines of the older or counterflow type, the simple uniflow engine operating with saturated steam and non-condensing, is able to surpass in economy of steam consumption the compound counterflow engine when operating under similar conditions. Also, that the simple uniflow engine operating non-condensing but with superheated steam will have approximately the same, or slightly less, steam consumption than the compound counterflow engine operating condensing but with saturated steam.

On the basis of these conclusions, it seems probable that the simple uniflow engine will prove a serious competitor of the compound counterflow type, since it is not only more economical in its use of steam, but also simpler in construction, and probably on that account lower in first cost.

LOCO. BOILER EXPLOSION

A RAILROAD locomotive boiler exploded recently and caused the death of five men and the injury of another. It will be seen that the crown sheet failed, which is a common method of failure with boilers of this type. The explosion is said to have been due to low water, which caused the crown sheet to become overheated. It is reported that the locomotive had been overhauled not long before, and that it had been in service but a day or two before the explosion occurred.

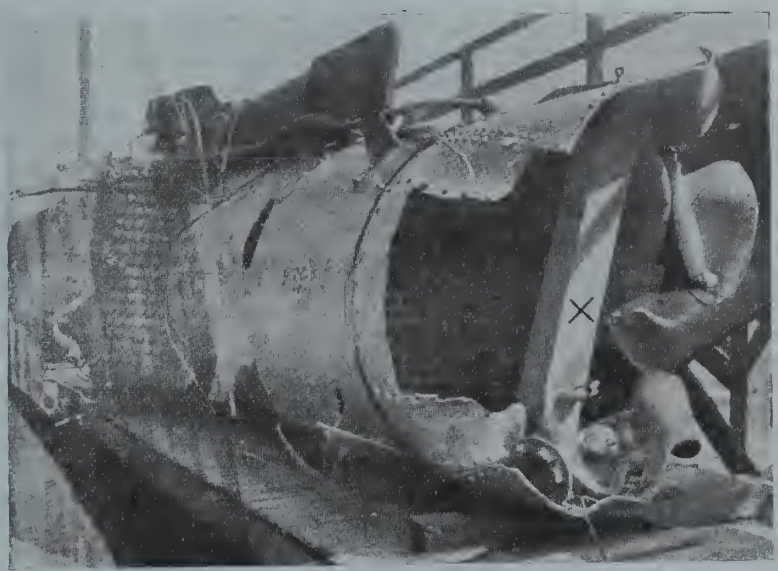

FIG. 2. FRONT END OF BOILER. NOTE RAILROAD TIE X WEDGED INTO SMOKEBOX.

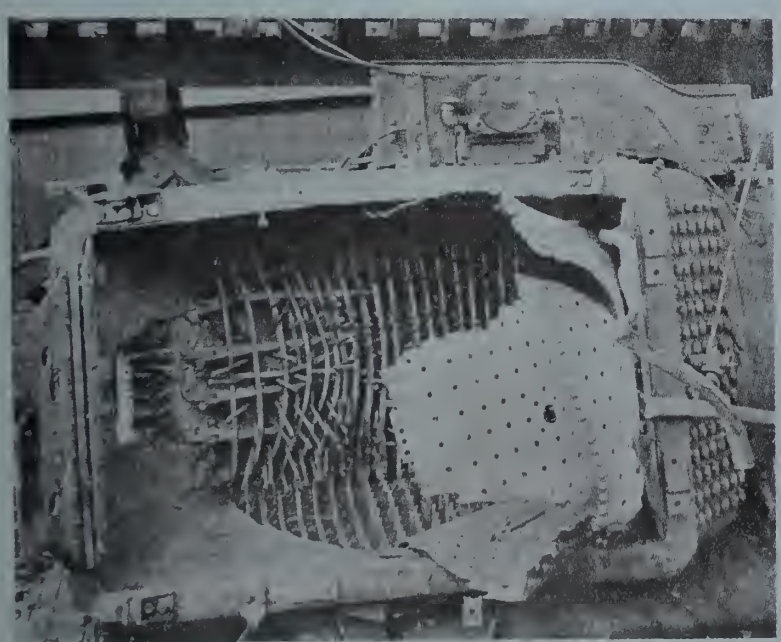

FIG. 1. SHOWING THE FURNACE AND CROWN SHEET.

The boiler was built in 1905. The waist or shell was 69½ inches in diameter, and there were 273 tubes, each 2 inches in diameter and 162½ inches in length. The working pressure was 205 pounds. We are informed says the Travelers Standard, that when the explosion occurred the boiler was torn from the locomotive trucks and was blown over a signal tower about 50 feet distant. It turned over twice during its flight, and landed about 124 feet from the spot where it started. At some time during its journey the front end of the boiler fell upon the right of way and cut off a railroad tie, which is shown wedged between the opposite sides of the front course of the boiler in Fig. 2. It is easy to imagine the extreme havoc that would have been wrought by the explosion if this had been a stationary boiler located in the boiler house of a power plant.

COAL VERSUS WOOD FUEL

By D. Street

THE rising cost of coal, as well as of other articles of all kinds necessary to industry has turned the attention of many users of coal to the possibilities of wood, and if the change is made from one class of fuel to the other certain necessary conditions must be carefully observed. The chemical composition of wood, when dried to 140 deg. Fahr. varies very little indeed, and the constituent parts of the various woods are as follows:—

FOR COAL VS. WOOD.

	Carbon	Hydrogen	Oxygen	Nitrogen
Beech	48.98	6.07	43.11	0.93
Oak	50.64	6.03	42.05	1.28
Birch	50.61	6.23	41.04	1.12
Aspen	50.31	6.32	42.39	0.98
Willow	51.75	6.19	10.98	0.98

The first three are hard woods, weighing about 50 lbs. per cubic foot, whilst the latter woods weigh about 35 lbs. so that the reputation of the heavier woods for producing more heat must arise from their greater density and smaller capacity for holding water. Their carbon and hydrogen content, per pound, is very much alike. The ash left by wood when completely burned varies from ½ to over 3 per cent.

Moisture in Wood

Wood, when felled, contains from 20 to 50 per cent. of water, and seldom even after storing has less than 15 per cent. while if brought during the rains it may have very much more. A purchaser should therefore be very careful to ascertain the amount of water in his fuel to adjust the price properly. Wet wood, when burnt by raising half of its weight in steam that passes uselessly into the chimney, may make a very unsatisfactory fuel. The amount of moisture in a supply of wood fuel may be ascertained by splitting several logs through the middle and planing an equal quantity of shavings from each. Mix the shavings and select a one pound sample to be dried in the air until it ceases to lose weight, and another pound to be dried carefully above the boiler, noting the temperature of the air among the shavings and weighing. The experimenter will then be able to ascertain the percentage of moisture in the wood when air-dried and stove-dried. In England dry wood is worth, for the purpose of steam raising, half its weight in English coal having only 5 per cent. of ash, but when the ash in coal amounts to 22 per cent, the ratios of value are considerable altered in favour of wood.

Much depends on the way in which wood is burnt. If used in large pieces there will be considerable spaces between them, and the total amount in the state of combustion will be reduced. There may also be an excess of air drawn through the fire. The fire bed, when wood is used, is more difficult to manage, and for the control of the draught it is well to have a door on the ashpit. When using wood fuel it is desirable to have the means of cutting it up cheaply into pieces of such a size as may be fed easily into the fire and properly managed for burning. A Cornish boiler has a more convenient furnace for wood burning than a Lancashire one on account of the greater size of the furnace flue and greater flame space, but an exterior furnace may be built to greater advantage for room, and is largely used in countries where wood is the only fuel obtainable.

COMPARATIVE BOILER EFFICIENCY TESTS CONDUCTED AT THE PLANT OF GORDON, IRONSIDE & FARES, LTD., WINNIPEG.

OBJECT OF TESTS: TO DETERMINE EFFICIENCY OF THE "GALT" SPRINKLER STOKER OVER HAND FIRING, USING LOW GRADE COAL.

	HAND FIRING.	"GALT" SPRINKLER STOKER.
Kind of fuel used on test	3 of anthracite dust to 1 part bitumin's slack.	4 of anthracite dust to 1 part bitumin's slack.
Type and horse power of boiler.....	Ret. tubular, 125 H.P.	Ret. tubular, 125 H.P.
Duration and date of test.....	(July 3rd) 8 Hours	(June 30) 8 Hours
Average steam pressure—gauge.....	100 Lbs.	100 Lbs.
Average thickness of fire.....	6 Inches	3 Inches
Average temperature of feed water.....	187°	180°
Total cost of coal used on test.....	$16.95	$10.84
Total weight of coal used on test.....	6,800 Lbs.	4,500 Lbs.
Total water evaporated.....	37,590 "	36,500 "
Evaporation per lb. of coal (as fired).....	5.5 "	8.1 "
Factor of evaporation.....	1.068	1.073
Evaporation per lb. of coal from and at 212°	5.9 Lbs.	8.7 Lbs.
Evaporation per lb. of combustible from and at 212°	6.7 "	10.08 "
Per cent. of ashes and refuse.....	15%	13%
Equivalent total water evaporated from and at 212°	40,146 Lbs.	39,164 Lbs.
Cost of fuel to evaporate 1,000 lbs. of water..	45.1c	29.6c
Cost of fuel to evaporate 1,000 lbs. of water at 212°	42.2c	27.6c
Chemical analysis of fuel B.T.U. per lb.....	12.000 B.T.U.	12.000 B.T.U.
Combined efficiency of boiler and furnace....	47.5%	70%
Total heat derived in B.T.U. per lb. of fuel...	5.700 B.T.U.	8.404 B.T.U.
Actual boiler horse power developed per hr...	145	142
Grate area	30 Sq. Ft.	30 Sq. Ft.
Coal burned per sq. ft. of grate per hour.....	28.3 Lbs.	18.7 Lbs.
Nature of draft employed (under grate)	Forced	Forced

The above tests were made by John L. Tully, Mechanical Superintendent of Gordon, Ironside & Fares. The water and coal used on each test was accurately weighed and recorded, and every precaution taken to have both tests conducted under exactly equal conditions.

It will be noticed that 3 parts anthracite dust to 1 part bituminous slack was used on the hand fired test, and 4 parts of the former to 1 part of the latter with the stoker. With hand firing the steam pressure could not be maintained, using the 4 to 1 mixture.

HOW TO PREPARE WHITEWASH

IN view of the fact that boiler room walls and ceilings and, in not a few instances, those of engine rooms are periodically given a coat of whitewash, the accompanying data covering the preparation of the latter may be found handy for reference and for checking its constituent when the work is being done under contract.

Slake half a bushel of lime with hot water, stirring continuously while slaking; strain it and add one peck of salt dissolved in warm water. The proper consistency of whitewash is a thin paste, and water will have to be added to secure this consistency after mixing the dissolved salt with the whitewash.

To each 12-quart pail of whitewash composed as above, add a good sized handful of Portland cement and a teaspoonful of ultra-marine blue. The cement and blue should be added only as the whitewash is being used, and should be thoroughly stirred into the whitewash; otherwise, when applied it will be streaked.

Where there are pipes or other equipment in rooms to be whitewashed that will rust, do not use salt in the mixture around the piping.

Do not put on too thick a coat — just enough to cover the surface in good shape —then allow from one to three days for drying. If you dry the whitewash out too quickly it will flake or brush off very easily; on the other hand, a very slow drying will allow the water to soak into the wood and may cause unpleasant odors.

Whitewash containing Portland cement must be used without delay.

OUR UNDEVELOPED WATER POWERS

WHEN the present survey of Canada's natural resources are completed under the auspices of the Canadian Pacific Railway, it will doubtless contain a great deal of new information relative to the undeveloped waterpower of Manitoba, Saskatchewan and Alberta. Investigations already made by a sub-department of the Ministry of the Interior, it is claimed, establish the fact that in the Saskatchewan River, with its tributaries furnishing the water arteries of a vast expanse of country, and in the Winnipeg River and other streams emptying into Lake Winnipeg, there is hydro-electric energy sufficient to harness 1,172,000 horse-power.

In the upper reaches of these provinces, the Athabasca, Peace and Churchill Rivers, with a number of other large streams, in their long course to the Arctic Ocean and Hudson Bay, afford new sources of energy equivalent to at least 5,500,000 horse-power. Out of this aggregate of over 1,000,000 horse-power, only a little over 100,000 has been employed. Manufacturers, it is expected, after the war, will take on new life at Calgary, within 100 miles of the Selkirk range of mountains. The Bow River, from which 31,000 horse-power has been drawn, has at least 75,000 undeveloped reserve power available for the industries of that city.

The Development and Application of Centrifugal Pumps

By H. S. Budd *

Centrifugal pumps by reason of their compactness of design, smoothness of operation, few constituent parts all of which are of comparatively simple and rugged construction, and freedom from shock and water hammer, make a powerful appeal to users of pumping machinery generally; and that their adoption to a wide range of service has in the past been productive of good results, is shown by the growing tendency to broaden their application scope still further, while intensifying their installation where already operative.

CONTRARY to the belief held by some that the centrifugal pump is a modern invention, it is in fact quite an old one and of obscure origin. One authority informs us as follows:—

FIG. 1. BELT-DRIVEN, SINGLE SUCTION, OPEN IMPELLER PUMP.

"The first pump of this kind which attracted notice was one exhibited by J. P. Appold in 1851, and its special features have been retained in the best pumps since constructed. Appold's pump raised continuously a volume of water equal to 1,400 times its own capacity per minute. It had no valve and it permitted the passage of solid bodies, such as walnuts and oranges, without obstructing its working. Its efficiency was also found to be good."

For many years the centrifugal pump was considered useful only for handling large quantities of water at low heads and was uneconomical to operate. The development of the steam engine and its application to direct acting steam pumps kept the centrifugal in the back ground where it remained almost forgotten for many years. With the introduction of electricity and motor drives and, later on, steam turbines, however, there arose a demand for a pump that could be direct driven at comparatively high speeds, and the centrifugal pump has been improved and refined to meet this requirement. This development has been along purely scientific lines with quite wonderful results, until these pumps now operate with surprisingly good performance and economy on nearly all classes of both high and low head service for which only reciprocating pumps had formerly been used.

The simplicity and compactness of construction, smoothness of operation and freedom from shock and water hammer all appeal immediately to those familiar with pumping machinery. As these units consist of but few parts, all of comparatively simple and rugged construction, with total absence of reciprocating parts, water valves, etc., they present quite a contrast to recriprocating pumps, both in attendance required and cost of repairs, and in most cases will operate with a considerable saving in power consumed.

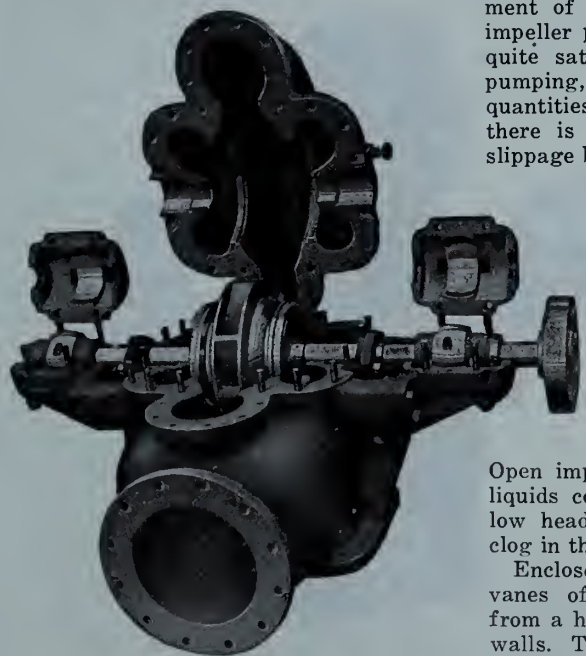

FIG. 2. DOUBLE SUCTION VOLUTE PUMP WITH CASING OPEN TO SHOW ACCESSIBILITY.

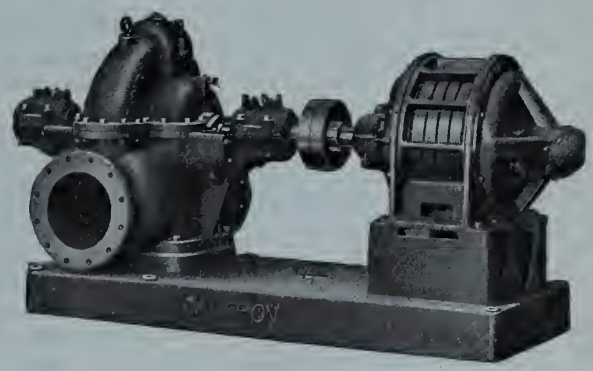

FIG. 3. MOTOR DRIVEN DOUBLE SUCTION VOLUTE PUMP.

Centrifugal Pump Types

Centrifugal pumps as built to-day are of two general classes, namely, open and enclosed impeller types, depending on the type of impeller used.

Open impellers consist of a number of arms or vanes radiating from a hub in the manner of an ordinary centrifugal blower. The sides of the vanes are usually faced off and run close to the walls of the casting on both sides in order to prevent, as far as possible, the slippage of the liquid being pumped. By refinement of design and construction, open impeller pumps have been made to show quite satisfactory results on low head pumping, especially in delivering large quantities at a head of a few feet, but there is always a large percentage of slippage between the impeller and casing, as well as excessive skin friction and internal disturbance which becomes more pronounced as the operating head is increased. These losses are variable quantities and make high efficiency impossible; the designer cannot, therefore, predict with any great degree of accuracy the ultimate performance of the pump. Open impellers are adapted to handling liquids containing some solid matter on low heads that would tend to hand or clog in the inclosed impeller types.

Enclosed impellers consist of blades or vanes of suitable currature radiating from a hub and enclosed by two discs or walls. The liquid to be pumped enters at centre or eye of the impeller around the shaft on either one or both sides, pending on whether it is of single or double suction type, and passes through the wheel in channels formed by the walls and vanes. Double suction impellers which

*Sales Engineer, the A. S. Cameron Steam Pump Works, Chicago, Ill.

are subjected to the same pressure conditions on either side, are automatically balanced against thrust along the line of the shaft for all ordinarly operating heads. Single suction impellers are not so comparatively balanced an dtherefore require end thrust bearings.

As the enclosed impeller handles the liquid being pumped through confined passages or channels of definite form with a limited amount of disturbance or leakage, a capable designer can quite accurately control the performance of the pump over a broad range of operation. For this reason the enclosed impellers are used for all medium and high head pumping equipment and when high efficiency is desirable.

Single Stage Pumps

A single stage pump contains one impeller and can be built for almost any capacity and reasonably high head with efficiency results, the larger sizes being more economical, of course, than the smaller. The greater the head created by a single impeller, the greater will be the difference in pressure between the suction and discharge chambers of the pump. This is accompanied by a greater internal slippage and leakage and more rapid destruction of the internal parts, and, therefore, is one of the factors that determine the greatest pressure or head allowable per impeller or stage.

Multi-Stage Pumps

For higher heads, multi-stage or turbine pumps are used. These consist of two or more enclosed impellers on the same shaft, running in a casing with passages so arranged as to lead the liquid through the several impellers in succession, each one adding its equal share of the total pressure desired. By this means, pressures of several hundred pounds may be obtained from a single pump, the limit depending on the mechanical limitations of design, strength of materials used and their resistance to abrasions by the liquid at high velocity. In multi-stage pumps the liquid discharged at high velocity from all, but the last impeller must be abruptly turned through 180 degs. to enter the eye of the succeeding one, and suitable vanes known as diffusers are provided to reduce the speed of this water as far as possible, and convert it into pressure as soon as it leaves the impeller, so that it may be conducted into the succeeding one with the least disturbance and impact on the walls of the casing.

All multi-stage pumps require some means of maintaining correct alignment of the rotating element with the passages in the casing and of equalizing any end thrust that may be present. In pumps handling clean fresh water, this is best accomplished by means of an internal hydraulic device in which the thrust is carried on a body of water confined by a suitable piston or diaphragm mounted on the shaft. This device is quite simple in construction, yet it automatically and promptly adjusts itself to varying load conditions, and being a water bearing with no metal to metal contact, operates with practically no loss of power. Where the liquid being pumped carries grit or solid matter that would tend to wear the parts of the hydraulic balancing device rapidly, a step bearing of the Kingsbury or marine thrust type external to the casing should be substituted.

Design and Construction

The requisites of a centrifugal pump are, first, that it shall be well and suitably constructed mechanically, and secondly, that its performance shall comply with all the service requirements and show the highest efficiency possible on that service. The pump should be of strong and substantial construction in all parts, free from vibration of the rotating elements with large and well oiled and close fitting bearings, both to insure continuous operation and to preserve the fine running clearness within the casing which serve to prevent internal leakage from the spaces of higher to lower pressures. The material of which the various parts are made should be well selected for the duty to be performed, and the general design thoroughly accessible for inspection of the interior and renewal of parts.

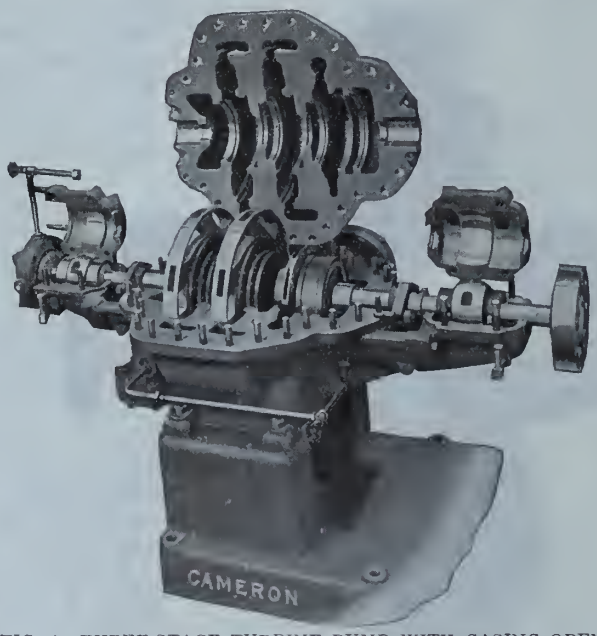

FIG. 4. THREE-STAGE TURBINE PUMP WITH CASING OPEN TO SHOW ACCESSIBILITY.

The operating principle of a centrifugal pump is quite simple. The liquid pumped is accelerated by passing it through a revolving impeller, creating both pressure and velocity, the velocity being then converted into pressure in the stationary discharge passages. However, it becomes a very complex problem to design and build a pump to deliver a given quantity of liquid against a specific head at a definite fixed speed and to accomplish same at the highest efficiency. A capable designer can predict within a small percentage of error both the performance and the brake horsepower required not only at the normal operating point, but over a range, from a condition of free discharge against no head, to a closed discharge and no liquid flowing. The solution of these problems requires a thorough knowledge of the theory of centrifugal pumps and an analysis of a very great amount of accurate data obtained experimentally from pumps of similar characteristics.

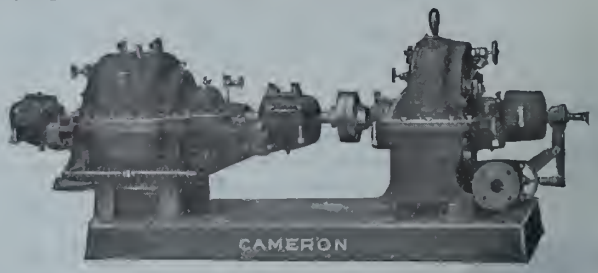

FIG. 5. STEAM TURBINE DRIVEN, THREE-STAGE TURBINE PUMP.

The production of an efficient and altogether satisfactory pump involves not only a correctly designed impeller, but the casing also must be of such mould and cross-section that changes in velocity of the liquid will take place gradually and without shock and disturbance. It requires very careful and accurate shop work to put into effect all these details so carefully worked out by the designer, in order that the finished pump may fulfill all the requirements specified, and it is, therefore, very essential that each pump be subjected to a performance test after completion, in order that any discrepancies may be detected and properly corrected. Each installation is a problem by itself and must be treated as such, if definite results and highest efficiency are to be realized.

Application and Uses

Centrifugal pumps may be driven direct or through belt or gear from electric motor, steam turbine or engine, or other source of power, as best suits the requirements of the particular installation. Direct connected to steam turbines they make highly satisfactory steam operated units. They operate on less steam and require less lubricating oil than ordinary steam pumps. They occupy small space, and their advantages in freedom from valves, valve motion, and rubbing parts are all too evident to need further comment.

Water Works Service.

Motor driven centrifugal pumps have met with great favor on water works service in small towns and villages. When operated in connection with stand pipe or

elevated tank, they may be arranged to be automatically started and stopped by means of a pressure regulator or float switch. When used with a direct pressure system, the pump or pumps may be run continuously maintaining the pressure and delivering only such water as is drawn from the mains. In localities where a part of the district supplied is on a higher elevation or some distance away requiring an excess pressure, it is found expedient to maintain a domestic pressure at the pumping station suitable for the greatest demand and to insert a centrifugal in the main that supplies the higher pressure. Such an installation is known as a booster pump and it may float on the line continuously adding a fairly constant net pressure irrespective of the amount drawn from that line. It is often the practice to use a moderate pressure in water mains for domestic service and to increase it materially in case of fire. As motor driven centrifugal pumps are preferably constant speed machines and, therefore, suitable for one pressure only, it is quite common in cases of this kind to install two or three duplicate pumps designed for domestic service and operating two in series to obtain increased pressure for fire service.

Quite a large number of turbine driven centrifugal pumps, running condensing, have been installed where in former years only crank and flywheel pumps would have been considered, and the improvement both as to reliability and economy has been so marked that at present their performance rivals the best triple expansion crank and flywheel pumping engines in total yearly operating cost, when due allowance is made for all interest and standing charges on the capital involved. These charges, of course, greatly favor the centrifugal unit on account of its comparative low first cost, together with that of the smaller building, lighter foundation, etc.

Boiler Feeding

Among the many uses of the centrifugal pump, boiler feeding is a service for which it is ideally suited. The pump is usually driven electrically or by steam turbine, whichever is best suited to the particular installation. In operation the motor-driven boiler feeder is generally allowed to run continuously at full speed, maintaining a fairly constant pressure on the feed line for a considerable range of capacity. The amount of water fed to the boiler may be controlled by a throttle valve in the feed line without danger of creating a dangerous increase in the latter, as the centrifugal will not build up a pressure exceeding 15% to 20% above normal pressure, even when the discharge is entirely closed.

Steam turbine driven boiler feeders are sometimes operated in this manner also, but they are more often equipped with pressure regulators of a type similar to those used on ordinary steam pumps to maintain a constant differential between the steam and the feed line water pressures, especially where the variation in steam pressure is considerable. Whether driven by electric motors or turbines, the feed water to the boiler can be regulated without reference to the pump, and further, there are no valves or large packings to be maintained, nor is there danger of water hammer and breakage in case of loss of suction as with reciprocating pumps.

Efficiency.

The efficiency of any centrifugal pump is highest at only one combination of head and capacity for each change of speed, and, therefore, if a pump is operated on a head or at a speed other than that for which it is designed, the amount of delivery and power required can be only approximately predicted. At the same time, the efficiency would likely be very low, making the installation quite unsatisfactory for the work it was intended to do, as well as expensive in cost of power for driving.

Low pump efficiency means increased power required, and even though it be but a few per cent. it must be borne in mind that this excess horsepower is consumed continuously while the pump is in operation and will total up to a considerable sum in a year's time, representing in dollars and cents more than the difference in cost of a well designed as against an inferior pump, or equalling the interest and depreciation on the entire installation for the same period. In like manner, the saving made by the better pump when compared with the common type, will invariably pay back its entire cost in a comparatively short time.

Wearing Parts

There are a few parts of the enclosed impeller type of pump that are subject to wear, namely, that part of the casing which makes a running joint with the impelled, and the sections of the shaft within the stuffing boxes and the bearings. If these wearing surfaces are provided with renewable parts that can be replaced at small expense, the main and more costly parts, being protected, will last almost indefinitely, ensuring a low cost of maintenance. Wearing rings secured in the casing around the impeller inlet protect the case from wear at this point, and a similar pair of rings made of bronze and secured on the impeller protect it from wear also. Bronze sleeves secured on the shaft and passing out through the stuffing boxes relieve it entirely from scoring by the jacking, or rusting. By supplying the bearings with removable ring-oiled split babbitt-lined shells of spherically seated type which may be easily slipped out when worn, and either rebabbitted or replaced by a new set, the alignment of the rotating element will not be disturbed, and the close fit between the impeller and case so necessary to prevent internal leakage, will be preserved. These features will be clearly illustrated by the views that will be shown on the screen a little later on.

Operating Conditions

It will be readily appreciated from the foregoing that in building a centrifugal pump for a particular installation, it is essential that the conditions of head, capacity and speed be accurately determined and furnished to the designer, together with any special requirements involved, especially if the highest efficiency is expected. It is not to be understood from this that the centrifugal pump is an extremely sensitive affair that will be efficient at one particular combination of head and capacity only, and of low economy when these ideal conditions do not obtain. The efficiency will remain nearly constant for a small variation in head both above and below the normal, the capacity varying inversely as the head, consequently it is usually safer to figure the total head a trifle high and design the pump accordingly, and then if the head is actually less, a slight increased capacity will result, which is not usually objectionable. Very often two or more conditions of head or capacity can be obtained from a pump of special design running at constant speed with a satisfactory balance of efficiency, and with provision for some speed variation the possibilities of designing for varying service are greatly increased.

Total Head

The total head on which a pump has to operate is made up as follows: Vertical static suction lift from the level of the liquid in the well or sump to the centre of the pump; static discharge head measured vertically from the centre of the pump to the point of discharge; friction in the piping, valves and elbows of both suction and discharge lines, velocity head, and entrance head. In addition the pump must overcome the loss of head within itself, but the builder only is concerned in this, and the efficiency of the pump is the ratio of the theoretical power required in raising the given quantity of liquid against the total head, to the sum of this power plus the hydraulic losses in the pump, and the friction in bearings and stuffing boxes. This sum is known as pump horsepower.

Effect of Speed Variation.

Both the total head and the capacity of a centrifugal pump are quite sensitive to speed variation, therefore great care must be exercised in determining the speed at which a pump is to operate in order that it may be designed accordingly. This is particularly essential when the pump is to be direct connected to a constant speed afternating current motor of which the speed at full load is several per cent. lower than at no load, and there is no convenient way of altering the speed of such a motor.

Priming

A centrifugal pump cannot raise a liquid to itself from a lower level without first being primed, because it possesses no positive displacement feature and, therefore, both the pump case and suction piping must be entirely filled before starting. Priming may be accomplished either by providing a good valve on the lower end of the suction line and filling the pump and suction piping from the discharge line or other source, or by drawing the liquid up into the pump

through the suction pipe by exhausting the air from the top of the pump case. With this latter method, the discharge must be closed off by means of a gate-valve, and the foot valve may be dispensed with if desired, provided the pump is started while it is primed. The air may be withdrawn from the pump by means of a suction pump, steam injector, or other means of creating sufficient vacuum to entirely fill the pump case.

Suction Lift.

Once in operation, a centrifugal pump will handle water or other liquid of the same specific gravity and character at ordinary temperature on as great a suction life as a reciprocating pump, namely, about 26 feet at or near sea level, and provided the suction piping and pump are entirely free from air and air leaks. Because of the difficulty sometimes encountered in maintaining air-tight suction glands and piping, 18 feet is, however, usually considered the maximum commercial suction lift, and even less is advisable whenever possible.

The limit of suction lift decreases with the rise in temperature of the liquid on account of the increased vapor tension, and it is not advisable to undertake any suction lift with water at a temperature exceeding about 150 deg. Fah., but rather have the pump so located that the water will flow into it by gravity. When handling water at or near the boiling point, as in boiler feeding, the water should flow to the pump under a head of from 6 to 10 feet, and the suction piping should be as direct as possible and of large diameter to eliminate the formation of vapor. Vapor or air or other gas in the pump in considerable quantity will collect within the suction opening of the impeller, being the point of least pressure, and impede the passage of the liquid, reducing the capacity of the pump, and at times causing it to lose its suction entirely.

Size of Piping

Bearing in mind the marked advantage of small suction lift, the intake pipe should be as short and direct as possible, with absolutely tight joints. It is usual to make the intake pipe and foot valve at least one size larger than the pump inlet to reduce friction, which, of course, adds to the suction lift. As the basic principles of the centrifugal pump require the liquid to be handled at high velocity, the suction and discharge openings are much smaller than are usual in reciprocating pumps of equal capacity, and the sizes of both the intake and discharge pipe lines should be determined from the amount of friction in the required length, which can be learned by referring to standard published friction tables.

Installation.

Centrifugal pump installations are usually provided with a gate valve in the discharge to shut the pump off from the line when not in use, or when open for inspection. There is nothing in a centrifugal to hinder the liquid flowing backward through it from the discharge line when not in operation, and consequently in cse of a sudden shutting-off of the power, the impeller acting as a water turbine, may be revolved backward at a speed dangerous to both the pump and prime mover. A foot valve on the intake pipe will prevent this occurrence, or if this is not provided, a check valve should be located in the discharge. Where the operating pressure is great and a foot valve is employed, there should also be a check in the discharge to reduce the shock on the pump case when the foot valve seats. The check valve should be provided with a by-pass in order to prime the pump should the foot valve leak.

In placing suction and discharge pipe lines they should be free from high spots or loops forming pockets in which entrained air may accumulate, as the air bubbles thus formed will offer considerable resistance to the movement of the liquid by obstructing its passage, and in case of the suction pipe they are liable to enter the pump in such quantity as to cause loss of suction entirely.

LEATHER BELTING NOTES

IN the choice of a belt, the first consideration is that it be made from a good hide. Some indicative opinion may be had by cutting a thin shaving from the samples offered, and tearing them between the fingers. This will enable even the unskilled to form an opinion as to how much of his purchase is leather, and how much simply weight-making material.

Leather belts lose a good deal of their strength and nature unless impermeated with a certain amount of oil. Good quality cod oil is largely used for this purpose. An ordinary belt thus lubricated, develops a stretching propensity, which is, of course, both troublesome and wasteful. The problem, therefore, is to secure the admittedly advantageous features of "lubrication without stretch." The solution is obvious—Stretch the belt fully before application.

The ultimate tensile strength of belting is not generally a factor in power transmission calculations. It may be reckoned at an average of, say, 3,500 pounds per square inch. Variation in ultimate strength is due not only to possible variation in the quality of the material, but to want of its homogeneity as well. The ultimate strength of a laced joint well put together should be taken at from 1,000 to 1,500 pounds per sq. inch, while that of a riveted joint may be taken as equal to one-half of the strength of the solid belt.

Adhesion of Belts

The motion transmitted by a belt is maintained solely by the frictional adhesion of the belt to the pulley rim. Belts do not communicate motion with precision on account of their liability to slip. The adhesive grip of a belt is greater on wooden than on cast iron rims.

A belt will slip just as readily on a pulley four feet in diameter as it will on a pulley two feet in diameter, provided are area of contact, the tension and the the conditions of the faces of the pulleys, number of feet the belt travels per minute, are the same in both cases. Causes of slippage are because belts are overloaded, dirty, clogged, dried up and neglected.

It stands to reason that while slip may be prevented by undue tightening, this is not the right method to make the belt do its full duty. A belt properly filled and of correct dimensions for its work, should break before slipping.

Engineers usually pay little attention to their belting except that which is giving immediate trouble. The ingredients of a leather, cotton, or camel's hair belt, Manila or hemp driving rope, slowly dry out and leave the contact surfaces hard. Unless something is added to replace these natural ingredients the belt or rope cannot be expected to grip the pulley close enough to transmit full load.

Creep of Belt

By creep of belt is meant its stretching and contracting propensity as it passes over the pulleys, and is due to inherent elasticity and nature of load. The net result is a continuous creep or shifting of the belt around the pulleys in a direction opposite to that in which the belt runs. Belt creep in practice is usually kept within a one per cent. limit, and to make certain of its attainment, the working strain for best material belt body and substantial joint is taken at 40 pounds per inch width single belt, 70 and 100 ditto for double and treble belts respectively.

When a belt runs at a high velocity, centrifugal force produces tension in addition to that existing when the belt is at rest or moving at a low velocity. This diminishes the effective driving force. Double belts are less pliable than single belts and the centrifugal force is greater. Furthermore, the tension is seldom increased proportionately; for these reasons, double belts should not be expected to transmit more than 8-5ths the power of single belts.

THE following figures give the allowable rise in temperature adopted by the British makers of electric motors as a basis of capacity rating: Open, protected, enclosed-ventilated with large mesh and pipe-ventilated with forced draught, 72 deg. Fah., for the windings and cores in which they are embedded and 99 deg. Fah. for the commutators and slip rings; enclosed-ventilated with smaller mesh, drip-proof and pipe ventilated with own draught, 85 deg. Fah. for windings and cores and 99 deg. Fah. for commutators and slip rings; enclosed-ventilated with very small mesh, totally enclosed and flame-proof, 99 deg. Fah. for windings and cores, and for commutators and slip rings, 99 deg. Fah.

Good nature will often keep a plant running smoothly and cool when good oil will not.

REFRIGERATION DEPARTMENT

DIFFERENCES IN QUALITY OF AMMONIA

By A. F. Adams.

I WAS much interested in an article on the "Differences in Quality of Ammonia," in your June issue, and was pleased to see this subject brought into print, because, I believe, as refrigerating engineers, we do not know enough about the quality of ammonia which we use. The test bottle, as has been suggested is no criterion, as to purity of the gas.

Is there not some method, whereby the engineer can test the ammonia, which he is using to his own, and his employer's satisfaction, so that both may know what they are paying for? The bottle test in the past has largely been considered all that is necessary, to determine purity, and in some cases I have seen manufacturers of ammonia, supply test bottles for this very purpose.

One phase of the subject I should like to have aired in your columns is the advisability of using different makes of ammonia in the same plant; this is sometimes found necessary.

In British Columbia I find that there are at least five different brands of ammonia, some of which it is now impossible to obtain for various reasons. A friend of mine, found it necessary to add to the charge in his plant another make of ammonia, but found that his condenser pressure had gone up about twenty lbs., where it remained for a few days, after which the pressure returned to normal.

The agent who sold the ammonia gave as a reason that his ammonia being pure drove all impurities to the condenser, and that this usually happened wherever his ammonia was used.

Upon investigation it was found that both brands of ammonia were made by the same process. Another declared that two different brands of ammonia would not mix in the system, at least for some time.

At one plant I visited they were changing to another brand. The engineer in charge told me, that he could see no difference in the working of the plant, with the exception that he was now doing more work than formerly, but as several changes had been made, he could not state whether the increased work was due to the new brand of ammonia, or to the general changes that had been made. My own experience has been similar to this. I could see no difference in the working of the machines after adding to the change from another make.

I should like someone to give us an approximate temperature at which ammonia gas will disassociate. I have been in plants where a cloud of smoke could be seen rising from the discharge pipe. Again, do we as engineers know as much as we should about the purity of ammonia gas. to be of much benefit to us, or must we consult a chemist?

INSULATION OF COLD-STORAGE BUILDINGS.

REFRIGERATING engineers have during the last few years practically discarded the empty space—the so-called dead-air space—once extensively used for insulating purposes. Theoretically, a dead-air space is a poor conductor of heat, but the ordinary air space is not a dead-air space. As one side of the space becomes warmer than the other, the air immediately in contact with it becomes lighter on account of the increase in temperature, and at once ascends, while colder air from the other side takes its place. Thus we have a circulation of air within the space, and heat is carried from one side to the other by convection. Moreover, it is extremely difficult to get the work done properly when empty spaces are depended on for insulation. The slightest crack or opening, even a nail hole, tends to destroy the efficiency of this form of construction. In the insulation of wooden walls, the best practice at the present time provides for an outer and inner shell, as nearly as practicable impervious to air and dampness, with a space between to be filled with some non-conducting material. The width of the space will depend on the filling to be used and the temperature to be maintained in the storage room.

For a cold storage constructed of wood, there is no better material for filling spaces than planing-mill shavings. Where available at all, they are cheap; they are elastic and do not settle readily; but, most important of all, they can be obtained in a very dry condition, which is essential; and further, they do not absorb moisture readily after being placed in position. There may be some difficulty in obtaining a sufficient supply of shavings in places remote from manufacturing centres, but many of the large sash and door factories now pack shavings in bales, weighing about 75 pounds each, for convenience in shipping. The weight of shavings required to fill a given space will depend somewhat on the kind of wood from which they are made, and also to some extent on how tightly they are packed, but a fair average is from 7 to 9 lbs. per cubic foot of space. They should be packed sufficiently to prevent subsequent settling.

Sawdust versus Shavings.

Because it costs little or nothing and is readily available in most country districts, there has been a tendency to use sawdust for filling spaces in walls in small cold-storage buildings. We would point out, however, that it is not as satisfactory a material for this purpose as shavings, owing to the fact that, while shavings are cut from dry lumber, sawdust is cut from green timber and is generally more or less damp. The dampness destroys its insulating value and encourages the growth of mould and rot, resulting in musty odour in the storage room, which would be injurious to the food stored therein. The growth of mold and heating would also cause settling of the sawdust and would leave open spaces which weakens the insulation. It is very important, therefore, that sawdust which is used for filling walls must be as dry as possible or the storage will be very unsatisfactory, and will soon become unfit for storing perishable foods.

Insulation Must be Dry.

One of the problems in cold storage construction is to provide against moisture being absorbed by the materials composing the insulation. In the construction of small ice cold storages, moisture or dampness is more likely to come from the inside, and provision must be made to protect the insulation. It must be understood that dampness, as referred to in this connection, does not imply the presence of water in the ordinary sense, but simply the presence of moisture as we find it, say, in green lumber, as compared with dry or well-seasoned lumber. In a wooden wall filled with shavings, it is the shavings which must be protected from dampness. This can be done by using damp-proof paper between the sheathing, or boarding, on the inside of the walls.

Brick, Stone or Concrete Walls.

If it is desired to erect a building of brick, stone or concrete, such walls will only take the place of the outside finish of wooden walls, and the same insulation must be used inside the brick, stone or concrete. None of these materials have much insulating value, and as erected in an ordinary wall are just about equal, for that purpose, to two courses of lumber. Brick or cement absorb moisture readily, and unless they are given some special water-proofing treatment, the insulating quality of such a wall is rather low. The outside surfaces of brick walls

may be painted with some effect, but where shavings are to be used inside of brick or concrete, the inner surface may be coated with pitch, paraffin wax, or some of the patented coatings on the market. Coating walls with either pitch or paraffin in cold or even cool weather without special apparatus is a rather difficult operation, on account of the tendency of both substances to harden very quickly. In using pitch, care must be taken not to get tar, or any mixture of tar, which would be ruinous on account of its odour. Pitch is odourless when it hardens. If the inside surfaces of brick or concrete walls cannot be properly waterproofed, the next best plan is to put 1-inch furring strips on the wall, then one course of matched lumber, which will form the inside surface of the space to be filled. It will be all the better if the sheathing is covered with dampproof paper.—C. G., Cold Storage Bulletin.

DANGER OF FREE AMMONIA IN BRINE TANK.

THERE are two methods by which to effectively destroy free ammonia in brine; one mechanical, the other chemical. The first is accomplished by the use of heat, and the second by employing an acid, which, by the formation of a salt, neutralizes the free ammonia.

In employing either of these two methods, one should be altogether governed by the amount of free ammonia in the brine. In the mechanical method, the use of the steam condensers has been found most effective, by pumping the brine over such. This procedure should be repeated until most of the ammonia has been driven off. A small amount left in the brine is not at all injurious.

As far as the elimination of the ammonia in the brine by chemical method is concerned, such should be left to the care of a practical chemist. By analyzing the brine, the amount of free ammonia is ascertained. By submitting size of tank and the height of the brine, the amount of brine contained therein is found. Possessing these two items, the amount of acid required for neutralization of the ammonia can be easily determined. The acid should be applied in small amounts, close to the agitator, which ought to be run at the highest possible speed, so that the distribution of the acid will be effected as quickly as possible. After 36 hours of agitation, the brine should be analyzed, and if it still contains free ammonia, additional acid must be added until the brine remains slightly alkaline.

Ice manufacturers, up to the present time, have not been on the alert as to the danger of free ammonia, to its destructive power on metal—galvanized and ungalvanized, but undoubtedly the increase in the cost of such will awaken interest in this direction.

WEAR OF TURBINE BLADING.

IN the course of a recent paper on the Deterioration of Curtis' Rateau Turbine Blading, A. Fenwick arrived at the conclusion that there is no difficulty in choosing a material for moving blades which can be depended on to give fairly satisfactory results in particular stages. Five per cent. nickel steel, brass and aluminum bronze in suitable stages will have a life of 40,000 hours, and perhaps 50,000, or more, which, if the turbines are run continuously, means five or six years. It is probable that in the majority of power stations the running hours would be much less, and the number of years the blades would last will be correspondingly increased. One has to decide what constitutes a satisfactory life, and if we assume the turbine will be in use for 15 or 20 years, the ideal blade material is one which will do its work efficiently for this period. If long life can only be achieved by the use of expensive alloys, the cost of such material would have to be compared with the saving in maintenance which would result by its use.

With regard to the life of turbine plant, one has to consider the probability of future improvements, which might increase the efficiency of turbines to such an extent that it would pay to scrap existing plants and install new ones. One has to admit, however, that a very considerable advance in efficiency would have to be made to justify this course, and the uncertainty of a sufficient improvement is a further argument for better blading material. A saving of 1 per cent. in coal consumption on a 10,000-kilowatt set supplying 6,000,000 units per month may represent about $2,000 per annum.

With regard to inlet nozzles, it is clear that no reasonable expense should be spared in making these absolutely reliable; nozzles with thin cast iron vanes should be abolished, but if cast iron is used, the design should be such that there is no possibility of pieces becoming detached.

The guide blading in use on these turbines is clearly unsatisfactory, and the reader may wonder why this state of affairs has not been remedied long ago. The user is, however, largely in the hands of the turbine builder, and, further, if a mistake has been made in design or material in the original installation, three years or more must often elapse before ths is discovered, and an equivalent time is taken to prove the success or otherwise of any alteration. Incidentally, thousands of pounds are spent by the user in large installations in renewing defective blading and making good damage caused by broken pieces, collapsed rings, etc. This maintenance should be unnecessary, and for this reason the defects have been given in considerable detail.

While the author feels that mild steel is preferable to the high percentage nickel steel in use, it must be admitted that the latter has given good results in many cases. On the fourth diaphragm J steel has been used for the 10 000 h.-p. compressors 8 and 9, and in both cases blades cracked, while on compressor 7 H steel and is in good condition.

High percentage nickel steel has been more extensively used and for a much longer period than non-nickel steel. The latter material is in use on one generator turbine, and in this case considerable pitting has occurred. The evidence obtained on a 10,000 h.-p. compressor turbine is, however, very much in favour of mild steel, and there seems little doubt that it will prove the better material. The possible causes of deterioration are not conclusive; they may all be contributory to the general failure, and the inconsistency of results, particularly at different stations, makes the whole subject very puzzling. One is inclined to blame 30 per cent. nickel steel, because so much of it is in use and fails, and it may be that mild steel will also prove unsatisfactory through cracking or pitting.

Blades made from brass sheet and carefully fitted to retaining rings have been used for small turbines by some manufacturers, and various methods of attaching blades could be devised. The cast-in method used on the turbines described in this paper is, however, very simple and requires a minimum amount of machining and fitting, so that it would be preferable to retain this design if satisfactory results can be obtained.

The author believes that the position can be much improved by the use of thicker blades of mild or low percentage nickel steel, say, ⅜-in., or ¼-in. tapered, perhaps, on the outlet side to ⅛-in. Unfortunately, an alteration of this kind on a ring designed for 2 mm. blades reduces the area for steam passage somewhat. To obtain the same port area, the radial length of the guide blade would have to be greater, necessitating a longer moving blade.

BRITAIN'S MUNITIONS SUPPLY

IN the course of a review of the work of the Ministry of Munitions by Dr. Addison in the House of Commons, July 28, it was stated in regard to explosives that the capacity was now four times that of a year ago, and twenty-eight times that of March 1915. The shell supply, both in quantity and quality was adequate—in spite of the enormous expenditure during the last few weeks the stock of filled shell had only been reduced seven per cent., and premature bursts were almost negligible. "Tanks" of various types were under constant construction and development, and motor transport facilities were so great now that considerable help was being extended to the Allies in this respect.

Overseas munitions supplies had been received with gratifying regularity, losses due to submarine activities being only 5.9 per cent. of consignments.

Yearly steel production in Britain is expected to reach 12,000,000 tons by next March—it is now 10,000,000 tons as against 7,000,000 tons three years ago. An interesting point in this respect was the expected increase of 1¾ million tons due to the utilization of home ores in the making of basic steel. Gun ammunition costs had been reduced so as to effect of saving of over $200,000,000 on the year's bill for these supplies alone.

Association and Personal

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS' CONVENTION AND EXHIBITION

THE 28th annual convention of the Canadian Association of Stationary Engineers, held at Toronto on July 24, 25, 26 and 27, was up to the high standard of previous gatherings, both as regards the business transacted at sessions of delegates and the exhibit of power equipment and supplies. In the exhibition hall, about fifty manufacturers occupied booths. The C. A. S. E. have recently secured a Dominion Charter and will thus be enabled to extend the scope of its activities. The executive are endevavouring to arrange for provincial reciprocity in licenses, and it is hoped that enactment of graded certificates for the Province of Ontario will become effective during 1918. Legislation to this end has been inaugurated. The convention next year will be held at London, Ont.

The executive officers of the Association met in the Prince George Hotel, Toronto, on the evening preceding the Convention opening, treasurer A. W. Heath being the only absentee, through illness. On this occasion, committees were appointed as follows:—

Credential—D. W. Laver, C. Hooper, J. Ogle.

Mileage and per Diem—Messrs. Laver, Hooper and Ogle.

Good of the Order—W. H. Johnston, W. A. Sweet, J. W. McGrath, S. Balmfirth, T. J. Tait, J. F. Smith, R. Walker, R. McCrudden, Geo. Moll.

Ways and Means—E. R. Grandbois, D. Freedy, Jno. Brown, C. Ott, R. S. Wright.

Auditors—R. D. Smith, S. E. Cosford.

Convention and Exhibition Opening.

Due to the unavoidable absence of Mayor Church, it fell to the lot of C. A. S. E. Executive President Forbes and Earl F. Hetherington, president of the Exhibitors' Association, to welcome to Toronto the delegates, their ladies, and others interested in the welfare and objects embraced in the activities of both organizations. Messrs. Wickens (Dad) Keith, Peiler, McGhie, and Crouch also took a hand in the inauguration ceremony, which was brought to a close by the singing of the National Anthem.

At the opening session of the Convention, the President's address naturally came first, its outstanding features emphasizing the necessity for immediate enactment of a scheme of graded certificates for engineers and the establishment of provincial reciprocity relative to same. The recent Bill of Incorporation secured by the Association was also discussed. The minutes of last year's Convention at Montreal having been read, as also the reports of the Secretary and Treasurer, each of which were of a highly satisfactory nature and reflected creditably on the energies and activities of Messrs. Hale and Heath, the various committees went about their allotted work, which consumed the whole afternoon.

ENGINEERS' BOOT AND SHOE RACE, HAMILTON No. 2, C.A.S.E. PICNIC.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President.—Robert Dyson, Guelph, Ont.

President.—W. G. Forbes, Montreal, Que.

Vice-President.—Rodger F. Gofton, Kitchener, Ont.

Treasurer.—A. W. Heath, Hamilton, Ont.

Conductor.—William Cooke, Belleville, Ont.

Doorkeeper.—John W. Beasley, Chatham, Ont.

Secretary.—John H. Hale, Hamilton, Ont.

At the delegate sessions on Thursday, London, Ont., was given the honour of having next year's Convention, although Kitchener, Ont., gave the boosters for London a close run for it. Election of officers resulted as follows:—

Past president, W. G. Forbes, Montreal; president, R. F. Gofton, Kitchener; vice-president, W. Cooke, Belleville; secretary, J. H. Hale, Hamilton; treasurer, A. W. Heath, Hamilton; doorkeeper, Geo. Moll, London; conductor, S. Balmfirth, Toronto.

Past President Dyson installed the new officers, while Past President E. R. Grandbois acted as Grand Tyler. Presentations of jewels were made to Past President Forbes and Secretary Hale, the latter receiving two extra bars to his jewel and an increase of salary, as a mark of the Association's appreciation of his services during the past year, especially in developing and carrying through the Bill of Incorporation. A. M. Wickens made the presentations. Following the foregoing ceremonies, papers of an educational nature were read by Messrs. Forbes, Hale and Valiquet, of the Quebec Engineers' Examining Board.

The lady visitors were cared for during Convention week by Messrs. Williamson and Wickens. Aside from the trip to Niagara Falls, automobile rides, theatre parties, candy and ice cream treats were the specialties indulged in and enjoyed by them.

Entertainment Features

A well arranged entertainment programme provided a welcome relaxation from the business end of the convention, while the fine weather added materially to the success of this feature. The proximity of Niagara Falls to Toronto was taken advantage of and a most enjoyable day was spent there on the Wednesday. The party, which numbered about 180, embarked on the Cayuga at 7.30 a.m., and after a pleasant sail arrived at Lewiston, N.Y., where electric cars were taken to the Falls via the Gorge Route. The scenic beauty of this popular route was most impressive, particularly to those who had not been that way before. Upon arriving at Niagara Falls, N.Y., the party was taken in hand by William Adelbott, chief engineer of the Shredded Wheat Co., and a move made to the factory, where an excellent lunch was served. While in Niagara Falls, N.Y., the C. A. S. E. were the guests of the National Association of Stationary Engineers, who accorded the visiting party

a hearty welcome and left nothing undone to make the outing both pleasant and interesting.

At the conclusion of lunch, it had been arranged to inspect the factory, but as noon hour intervened, this part of the programme was deferred until later in the day. After a brief rest in the commodious reception rooms, a move was made to the Falls, and, in spite of the heat, few absentees were noticeable. At this point, the party scattered and went their devious ways. A considerable number, however, during the afternoon, returned to the Shredded Wheat plant and were conducted through same to witness the various stages of manufacture of shredded wheat. This was in many respects the most interesting feature of the trip and everyone was impressed by the air of cleanliness prevailing throughout. The Shredded Wheat Co. maintain a regular staff of guides for showing visitors round the plant, the latter being always welcome.

Owing to the great heat prevailing, much of the spare time was spent in an endeavor to keep cool, some making for the nearest shade trees, while others preferred the invigorating atmosphere surrounding electric fans. The return was made via Niagara Falls, Ont., or the Gorge Route, according to individual inclination; a few, however, did the thing in style in automobiles. The return trip across the lake was made on the Cayuga, leaving Queenston at 7.15 and Lewiston at 7.45 p.m. Although the boat was crowded, the party made merry, the proceedings being enlivened by an impromptu concert. Toronto was reached at 10.30 p.m. The weather was perfect and the trip was thoroughly enjoyed by everybody.

On Tuesday evening a smoking concert was held in the Victoria Hall,. Toronto, and, judging by the applause, the efforts of the entertainers were much appreciated. The principal items on the programme were a boxing bout by the Baker Bros.; music and songs by Jules Brazil; solos by James E. Fiddes and G. E. Cole; while Jack Armour's monologues were as usual very entertaining and mirth provoking.

An item not on the programme was pulled off at noon on Tuesday at the conclusion of the morning session of the Exhibition Committee. H. S. Stephens was presented with an umbrella and a framed photograph of the Exhibitors' Association officers as a slight token of appreciation for the assistance he has rendered at various times to the enterprise. L. H. Rummage was also presented with a framed photograph of the officers. The presentations were made by Jack Armour.

Exhibitors' Association Officers, 1917-1918

The exhibitors, at a meeting held on the Thursday morning, elected the following officers for the ensuing year:—

Past president, Earl F. Hetherington, Goldie & McCulloch Co., Galt, Ont.

President, Flight-Lieut. Lloyd Archibald, on active service with the R. F. C.

1st vice-President, C. W. Schrag, Bawden Pump Co., Toronto.

2nd vice-president, T. S. Mock, Jenkins Bros.

Secretary, Gordon C. Keith, "Canadian Manufacturer," Toronto.

Assistant secretary, L. H. Rummage, V. B. Anderson Co., Cleveland, Ohio.

Treasurer, B. G. Newton, "Power House," Toronto.

Chairman, Exhibition Committee, A. Betton, Jas. Morrison Brass Mfg. Co., Toronto.

Chairman, Entertainment Committee, H. J. Ramshaw, Mgr. Garlock Packing Co., Hamilton, Ont.

WHEELBARROW RACE. HAMILTON No. 2, C.A.S.E. PICNIC.

Exhibitors, Representatives and Exhibits

Geo. W. Cole, Ltd., Toronto, represented by G. W. Cole and G. E. Cole—Cole return trap system draining two low pressure radiators, lifting and boiler feed traps.

Boiler Repair & Grate Bar Co., Toronto, represented by A. Hett and C. W. Andrews—20th Century dumping and shaking grate.

Dart Union Co., Toronto, represented by J. B. Goff and James Rae—Dart unions.

Bawden Pump Co., Toronto, represented by C. N. Schrag and T. Jones—1,000-gallon stock pump and combined motor-driven condensate pump.

Allen General Supplies, Ltd., Toronto, represented by E. D. Wilkes, E. W. Nick and A. W. S. Roberts—Venturi meter recording apparatus. Northern Equipment Co. lines, "Copes" feed water control.

V. D. Anderson Co., Cleveland, represented by L. H. Rumage—Steam traps and other power specialities.

Canadian Powers Regulator Co., Toronto, represented by C. B. Owens and T. C. Brooker—Automatic temperature regulation.

Canadian Fairbanks-Morse Co., Montreal and Toronto, represented by P. E. Thring and G. Janes — Durabia, Palmetto and Manhattan packings, Pratt & Cady valves, "Foster" reducing valves, "Strong" traps, S K F ball bearings.

A. F. Bowser Co., Toronto, represented by T. H. Rhodes—Oil storage and filtration systems.

Canadian Allis-Chalmers, Ltd., Toronto, represented by W. H. Burbidge—"Squires" trap, literature covering Harrison Safety Boiler Works apparatus and illuminated interior factory views.

Canuck Supply Co., Montreal, represented by J. G. Dohn—Anchor packings, "Bruebacker" taps, dies and reamers, "Vim" packings and belting. W. S. metallic packing, railway supplies.

Garlock Packing Co., Hamilton, Ont., represented by N. A. Davis and H. J. Ramshaw—Garlock high-pressure and sheet packings, gaskets, pump valves. Model engine operating on compressed air, demonstrating packings.

Darling Bros., Montreal, represented by J. H. Wiseman—"Dexter" valve reseating machines, "Webster" heating systems, "Sylphon" traps, "Burnham" pumps, "Union" air-cooled air compressor, reducing and back-pressure valves, "Clarke" flexible couplings.

Dominion Belting Co., Hamilton, Ont., represented by J. Scott—"Maple Leaf" stitched cotton and duck beltings, belt dressings.

Goldie & McCulloch Co., Galt, Ont., represented by E. F. Hetherington—Photographs and literature, descriptive of engine and boiler installations.

The Canadian Manufacturer, Toronto, represented by G. C. Keith and C. A. Brandt.

Dearborn Chemical Co., Toronto, represented by J. L. Beebe, A. W. Crouch and J. Thompson—Boiler-feed water treatment.

Federal Engineering Co., Toronto, represented by G. H. Mowers—Samples of "Scandinavia," "Lanco," "Federal" and "Balata" beltings.

John W. Gates, Montreal—Boiler furnace blocks, fire brick arch.

James Morrison Mfg. Co., Toronto, represented by A. Betton—Extensive display of steam brass goods, valves, gauges, lubricators, injectors, whistles, engine-room telegraphs, etc.

France Packing Co., Tacony, Pa., represented by A. F. France—France metallic packings.

Jenkins Bros., Montreal, represented by Jas. S. Mock—Line of brass and iron body globe and gate valves.

Mason Regulator & Engineering Co., Montreal and Toronto, represented by H. L. Peiler, John Collins and E. T. Jeffrey—"Bundy" traps, "Ashton" and "Mason" valves, "Simms" heaters, Griscom-Russell Co. products, "Everlasting" blow-off valves, "Babbitt" adjustable sprocket wheel, venetian-blind grate, master steam gauge, etc.

Lunkenheimer Co., Cincinnati, Ohio,

represented by E. A. Wilkinson—Valves and lubricators.

Keystone Lubricating Co., Philadelphia, Pa., represented by H. W. Allen—Keystone greases.

Quaker City Rubber Co., Philadelphia, represented by G. M. Wilkinson—P.P.P. rod packings, "Eborite" sheet and stop valve packings, mechanical rubber goods.

C. B. Turner, Toronto, represented by C. B. Turner and J. Liston—Smoke abater, plastic boiler and furnace linings, boiler skimmer.

"**Power House**," Toronto, represented by B. G. Newton, A. G. Webster and M. H. Woods.

"**Power**," New York, represented by Jack Armour.

Lyman Tube & Supply Co., Montreal, represented by J. A. Fitzgerald—Golden glow headlight, "Baldwin" chains and sprockets, "Cyclone" chain hoists and trolleys, "Shelby" cold-drawn seamless steel tubings, "New Departure" ball bearings, "Nice" thrust collars, "Roundbrook" bushings, "Garton-Daniels" lightning arresters, "Lyman" metallic packing and elevator guide lubricators, etc.

Shell Bar Boico Supply Co., Toronto, represented by H. A. Stephens—Anticlinker grate bar, "Boico" boiler compound, "Fit it" welding compound for high-speed tool steel.

HAMILTON NO 2 C. A. S. E. ANNUAL PICNIC.

HAMILTON NO 2., Canadian Association of Stationary Engineers, held its annual basket picnic at Dundurn Park, the Ambitious City, on Saturday, Aug. 4. Ideal weather favored the afternoon's outing, and contributed materially to the otherwise enjoyable entertainment which the lodge executive had planned for those present. A program of sports was arranged, for which useful prizes were donated, and needless to say, the different events were enthusiastically entered into and keenly contested. Representative engineers were present from London, Stratford, Kitchener, Toronto, Galt, etc., on invitation of the Hamilton Lodge, and no doubt, all of them went away impressed with the idea that whatever other claims Hamilton No. 2 has to go-aheadness in matters pertaining to the craft welfare, and they are not few, for sociability and get-togetherness, she sets an example worth emulating. All of the "boys" were not able to be present, as was to be expected, otherwise all Hamilton must needs go on holiday, and of course, as fate would have it, Jack Hale, the popular Executive Secretary, was among those who perforce had to keep the "home fires burning."

Donors of Prizes

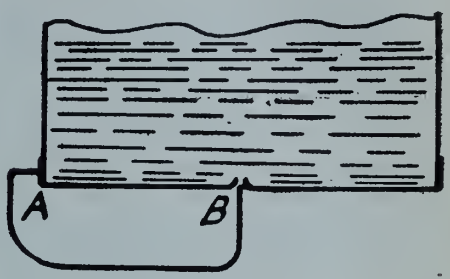
THREAD THE NEEDLE RACE, HAMILTON No. 2. C.A.S.E. PICNIC.

COOLING A TROUBLESOME BEARING

By J. E. McC.

TO aid in keeping a troublesome bearing cool, the oil recesses were capped with a tin cover, and a tomato can with a small hole punched in the centre of its bottom was suspended above the bearing and kept supplied with cold water. A small piece of waste placed on the tin cover was used for the water to drip onto, and from thence flow in different directions, instead of falling on the bare metal and flowing off in a single stream; too much waste is not advisable, as it was found that this would often prevent surface radiation from the metal and do more harm than good. The water kept the bearing cool enough for continuous operation, and having the hole in the centre



COOLING A TROUBLESOME BEARING.

of the can neutralized all rotary motion of the latter as its suspending cord twisted and untwisted with the changing weight. To open the hole if it became clogged, a wire was bent, as shown in the sketch. The distance from A to B was equal to the radius of the bottom of the can; therefore, with A placed against the side of the can at its bottom edge, the point B had only to swing to find the hole in the centre of same.

THE ELECTRIC TRUCK

IT IS STATED that the total value of electric trucks in the United States is approximately $36,000,000. If the same ratio in proportion to the population were obtained, Canada should possess electric trucks to the value of about $3,000,000. Information at hand shows that the total investment in electric trucks in the Dominion of Canada very likely does not exceed $300,000. From the above we can conclude that the field in Canada for the sale of electric trucks is very fertile and offers great possibilities either to the manufacturer or central station that is willing to put forth the proper amount of effort, says the report of the Canadian Electrical Association.

The principal reasons for the rapid success of the electric truck are the low up-keep and reliability. Supplementary reasons are the improvements in charging apparatus, the development of charging stations equipped with proper facilities, together with the increased capacity of storage batteries. In this connection it is interesting to note that the storage battery, as manufactured at present, possesses an average life of double that of a few years ago.

EXERCISING THE MENTAL FACULTIES.

HOW many workmen in the industrial world realize the loss they sustain by failing to make the most of the opportunities that each day has to offer. The vast majority of employees are apparently satisfied to "put in the time" at their daily task without much more than a passing thought as to the "why" or the "how" of its accomplishment. The successful achievement of one's duties is an essential factor in the solution of life's problem, nevertheless, it is equally if not more important that the full faculties of the mind be employed as a co-worker with, and a silent advisor of the eyes, ears and hands, to insure increased confidence in future effort.

Physical achievement unaccompanied by mental effort is but so much waste of energy. Thinking of one's work is necessary if the man is to become the master. The reasoning powers of the individual deteriorate more from disuse than overuse. Machinery that is constantly neglected will be ruined more rapidly than that in continual operation.

AVOID WASTE.

THE world war has taken so many producers from the sources of food supply that the world's consumption of food is greater than the amount available, and consequently, food reserves are being rapidly depleted. Millions of men are actively engaged in warfare and in the supply of munitions and equipment. They are fighting our battles and we must provide their food. Canada will produce all the food we can consume, but Canadians have never been known as a selfish race. Our Allies, therefore, are depending upon us for help and our people will unquestionably respond with generous hand.

Sir Robert Borden has said that Canada is in the war "to the last man and the last dollar." Canada is also in the war to the last pound of food. Canadians are their brothers' keepers, and will feed them, cost what it may. It is necessary, therefore, that we practise economy of the food supply. It is better to deny ourselves from choice than from necessity.

DEVELOP OUR WATER POWERS TO SAVE COAL

CANADA depends upon the United States for a large portion of her coal supply both for domestic and industrial purposes; she is therefore much interested in the coal conditions obtaining there. A recent communication from Secretary F. K. Lane, of the U.S. Dept. of the Interior shows how acute the situation has been made by the entrance of our neighbors into the war. One of the remedies urged, particularly applicable to Canada, is the immediate conservation of fuel by the efficient use of all available water power. Elimination of unnecessary consumption of coal is considered a problem of national interest and of immediate concern.

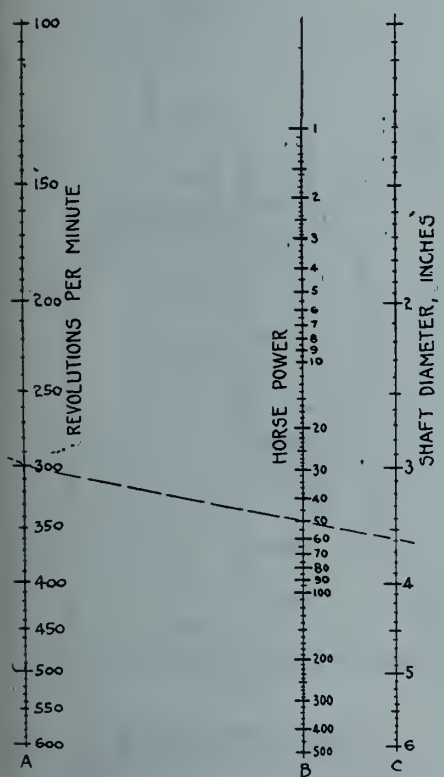
New power requirements should therefore be met, so far as practicable by utilization of hydro-electric energy; this would also apply to present steam generating energy consuming coal or oil in its production. Thus, all water available at water power plants should be utilized to produce energy up to the capacity of the works and the requirements of the population and industries within transmission distance of the site; every facility should also be given for the efficient development of new sites. In regions where water power can be made available, steam power plants should be operated only to carry loads in excess of those that can be carried by water power plants. The adoption of this course, in many cases, would mean cheaper operation, particularly in view of the rapidly increasing price of coal.

The Operators' Point of View

SHAFT DIAMETERS OF HIGH SPEED ENGINES.

By N. G. Near.

A RATHER peculiar thing about steam engines is the varying designs and sizes adopted by the different manufacturers. One manufacturer will use a 3½ inch shaft for a 50 h.p. engine running 300 r.p.m., whereas another manufacturer will use a 4 inch shaft at the same speed. There is no good reason why there should be this difference in size, aside from the fact



HIGH-SPEED ENGINE SHAFT DIAMETER CHART.

that one might prefer to use a greater factor of safety than the other. Since the cost of an engine is proportional to the weight, it is evident that the engine having the larger shaft is liable to weigh more than the engine having the lighter shaft and as a result the maker of the light engine can undersell the maker of the other. Inasmuch as both these engines give good dependable service when in actual use, however, it is difficult to tell which engine is "best." Perhaps the heavier engine will last longer, and perhaps not, in spite of its higher cost.

O. N. Trooien of the University of Wisconsin has studied steam engine design pretty thoroughly and has tabulated most of the common dimensions used in current steam engine design. Based on these tabulations he has developed curves or formulas which represent the average practice. It is allowable for us to use curves and formulas of this kind because we can rest assured that they will "work." They will give us engines and parts of engines that will be heavier than the lightest, and lighter than the heaviest. Mr. Trooien's study covered the best known engines only—not those that give trouble or are doomed to failure. As a result of this investigation, an "average" formula was developed for the shaft diameter of high speed centre crank engines. This is the formula:

$$d = 6.6 \sqrt[3]{(h.p. \div N)}$$

where d = diameter of the shaft in in.
h.p=the horse power of the engine
N=the revolutions per min. on the shaft.

Based on this formula, I have developed the chart herewith which will be found handy for determining any shaft diameter for any ordinary high speed engine. All that is necessary is to lay a straight-edge across as indicated by the dotted line drawn across the chart and the intersection with the "unknown column" gives the desired result. For exampe: What should be the diameter of a shaft for a 50 h.p. engine whose speed is 300 r.p.m.?

Connect the 300 (column A), with the 50 (column B), and continue the line until it cuts column C. The intersection with column C shows that the shaft diameter should be 3.6 inches. Should it be desired to make the diameter larger, of course, that could be done, at the same time, it would not be good policy to make the diameter smaller.

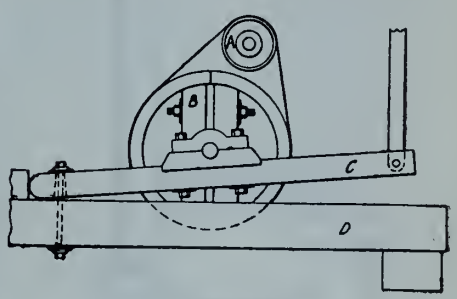
The chart will also be found useful for determining the safe load that can be imposed on your engine. Let us suppose, for instance, that the shaft in your engine is larger than necessary for carrying normal load, and this you can easily find out by using this chart. Thus if your shaft diameter is 3.6 inches, whereas it should be only 3 inches according to this chart, it is evident that little danger will result from increasing the pressure on the piston as far as the shaft itself is concerned. To be sure the other parts of the engine must be considered also before increasing the pressure or endeavoring to make a high-powered engine of it. One must be careful of the piston rod, the keys, the cylinder walls themselves, the head and crank end of the cylinder, etc. Every part that will be subjected to a greater stress must be given a proper examination and reckoning.

The range of this chart, it will be noted, is wide enough to care for almost any high speed engine, delivering all the way from 1 to 500 h.p. and covering all speeds from 100 to 600 r.p.m. It is very seldom that we see an engine with a shaft smaller than 1 inch or larger than 6 inches, and that is why, altogether, the chart can be considered complete and should be handy to keep on tap by engineers, students, designers, etc.

INTERESTING REVERSING GEAR

By J. Haliburton.

HAVING occasion to erect a certain mechanism in which the main shaft could be driven in either direction at will, and figuring that the probable outlay, to-



INTERESTING REVERSING GEAR.

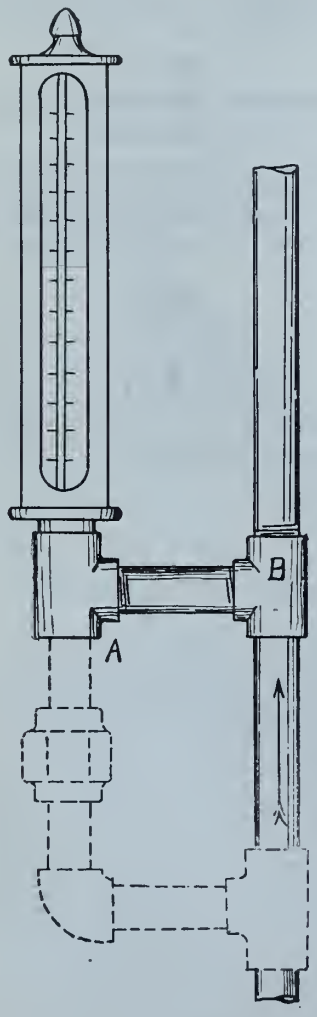
gether with the space required for reverse gears and clutches, and friction wheel trains, would entail prohibitive expense, the contrivance shown in the accompanying sketch was designed and constructed with very satisfactory results. The sketch A represents a gasoline engine pulley, while B is a wooden pulley used as a friction wheel when reversing, and as a belt pulley in the forward motion; one of the sills on which the machinery is supported is shown at D, while the beam C carries the end bracket of the driving shaft. The outer end of the beam C is connected to the operating lever by the link shown, the lever being in a horizontal position. With C raised, reverse motion is obtained, the

belt hanging by its own weight on the engine pulley A. When C is lowered, the weight of the shaft and pulley comes upon the belt, and forward or driving motion is obtained. The machinery is only loaded on the forward motion, so that the variation in the shaft alignment necessitated by the reversing operation is not sufficient to materially affect the working conditions. The length of the present shaft is about 5 feet, but a longer one could be used if aligning trouble should develop. By having the axis of B to one side of A, greater friction is obtained between the two pulleys when working in the reverse position. A suitable notch is provided to retain the mechanism in a neutral position when so desired. When operating in the reverse, and also during the accelerating period of the forward movement, a guide is necessary to keep the belt on the engine pulley. This arrangement has given very efficient service, and is as easily controlled as with a friction wheel train.

MAKING THERMOMETER REGISTER CORRECTLY

By K. Noble.

A THERMOMETER connected on a hot water pipe did not register correctly. It was connected as shown in sketch, a plug being in the end of the tee at A.



MAKING THERMOMETER REGISTER CORRECTLY.

The plug was removed and a pipe connected as shown by the dotted lines and everything was O.K. The flow of the hot water is shown by the arrows. Of course an angle end thermometer could have been secured and connected into tee B. However this would have partly obstructed the upright, but even if this would make no difference it cost less to make the change than it would to buy another thermometer.

FLOW OF STEAM THROUGH A GIVEN ORIFICE.

By N. G. Near.

NAPIER'S formula is well known the world over in engineering circles as a "pretty good one" for determining the flow of steam through an opening into the atmosphere. It may be applied nicely to finding the weight of steam used by a steam jet blower such as is often used for inducing draft in the chimney or for forcing air through the grates directly. In other words, where the drop in pressure is great, Napier's rule is excellent.

I have often related my experience with Napier's formula, which is sometimes doubted; but it is absolute truth. I measured the diameter of an orifice to to the hundredth of an inch by simply applying this rule, and I had never so much as seen the orifice until after my computations were all made. I weighed the water condensation from the steam that passed through the orifice and then determined the diameter of the orifice "backwards". The diameter was 0.16 of an inch. This is the formula

$$W = \frac{P\,A}{70}$$

, where W=the weight of steam passing through the orifice per second in pounds.

P=the absolute steam pressure in pounds per square inch.

A=the area of the orifice in square inches.

It is therefore evident that it wasn't much of a trick to use the formula backwards after knowing P and W.

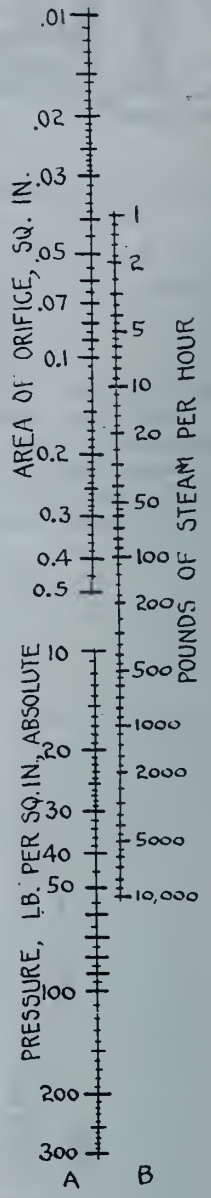
This little chart is based on that formula. It gives the weight of steam flowing through the orifice per hour instead of per second (see column B.).

To show how the chart is used let us take an example:—"Where the area of the orifice is .07 sq. in. and the steam pressure is 100 lb. per sq. in., how many pounds of steam flow through per hour?

Find the .07 in column A and the 100, also in column A. Then find the point midway these two figures. Directly opposite the mid-point is the answer, 360 pounds per hour.

It is a simple matter to find the mid-point. If you have a slip of paper handy just lay it alongside the scale and double it between the two points. Get the idea? The mid-point is at the crease, exactly. You can't beat the method with the finest pair of proportional dividers made. Of course, if you have a pair of dividers handy, use them, or use a ruler. There are many ways in which a line can be bisected but some of them are easier than others. What we all want, always, is the easiest way.

Again, should it be desired to find the area of orifice necessary to carry away 360 pounds of steam per hour with a



FLOW OF STEAM THROUGH A GIVEN ORIFICE.

steam pressure of 100 lb. per sq. in., you would go at it in the "opposite" manner. Find the distance from the 100 (column A) to the 360 (column B), and then measure upward that self-same distance from the 360. The answer, of course, is .07 sq. inches, pound in column A.

Another application of this rule or chart is to the soot blower. It will tell at a glance the weight of steam used per hour in blowing soot. From the result one can easily compute the cost of steam for soot blowing. That is a subject that has scarcely been discussed, if at all. Have you ever thought of it? Why not use the chart or formula once in a while, here and there, and determine a few of your costs? Maybe they are more than

you have estimated off-hand and maybe they are less.

Further, maybe you have a lot of leaky pipes in the plant. Maybe you have some cracked valves here and there which are purposely cracked to carry away the condensed steam. Maybe you feel that cracked valves are cheaper than a good steam trap. There are hundreds of ways, almost, which this chart can be used in and around a steam plant. Steam is expensive these days. It is growing more expensive right along. It should therefore be studied a bit more carefully. No harm can result from knowing the aproximate cost of every little operation where steam is used.

SIMPLE BOILER COMPOUND FEEDER

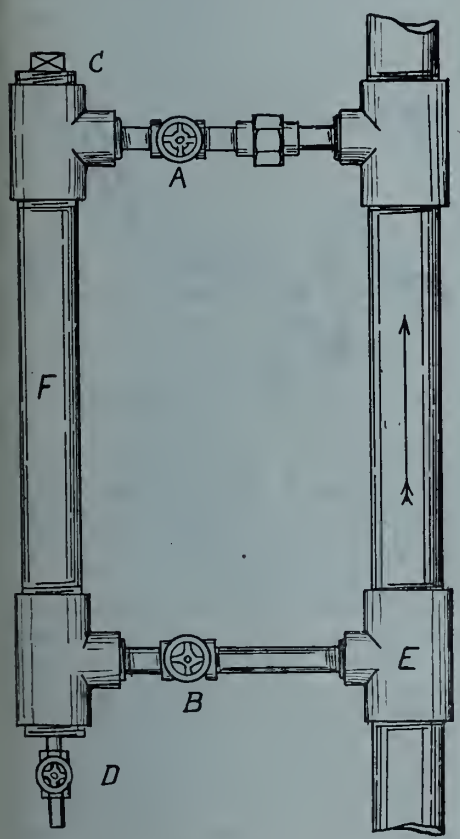
By J. Kington.

MANY engineers desire to feed dissolved soda solution or other boiler compound to the feed water after the water leaves the pump. Many devices for this purpose have been described. The idea shown in sketch is about as simple an arrangement as can be put together.

E is the feed water pipe from the pump.

A and B, are ⅜-in. pipe connections from the 2-in. pipe F to feed pipe E.

Close valves A and B, remove plug C.



SIMPLE BOILER COMPOUND FEEDER.

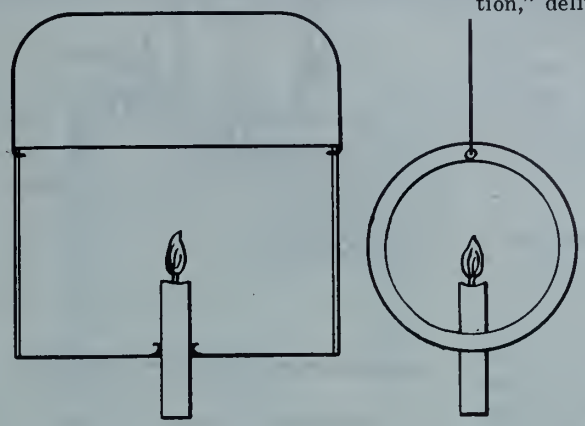
Open drip D and allow pipe F to empty. Close D, fill pipe F with the compound, screw in plug C, and slightly open A and B valves.

A nipple and valve can be used at C instead of the plug if desired. A glass can be attached to pipe F if the rate of flow of feed is wanted to be noted, but connected just as shown it has given satisfaction.

A TIN "CANDLESTICK"

By "Mac."

A CANDLE, a tin can, and a piece of stiff wire, can be evolved into a very serviceable make-shift lantern, especially for working under drips. A hole is made



A TIN CANDLESTICK.

in one side of the can midway between the ends and gradually enlarged until the candle can be pressed in, if possible leaving the tin in such a condition that a certain amount of spring is provided to retain the candle in position. Small holes are then punched in the ends, opposite the candle hole, and the wire bent to form a suitable handle. This simple device has been successfully used in places where an unprotected candle could not be depended on for light, and where even a carbide lamp with naked flame projected horizontally would occasionally be extinguished by the drip. A lantern having a glass chimney was practically out of the question, due to the breakage of the glass and subsequent extinguishing of the light by the water.

BRIQUETTED COAL AND COKE

By O. C.

THE utilisation of small coal by mixing it with pitch and compressing the mixture into briquette form has been carried on for many years, but not so extensively in this country as on the continent, where much of the surplus pitch from English gas-works was formerly shipped for that especial purpose. In Britain the industry is confined chiefly to the South Wales coalfield, which produced in 1914, 1,600,000 tons, of briquettes out of a total British Production of 1,840,000 tons. Ninety-six per cent. of the coal briquetted was small Welsh steam coal. In briquetting the coarsely ground coal is dried, mixed with 6.5 to 8 per cent., of its weight of pitch, passed through a disintegrator, thence to a heater to soften the binder, and on to the briquetting machine.

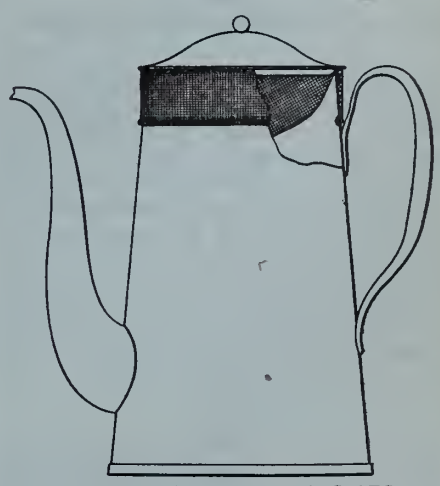
Of more recent date is the application of the briquetting process to coke, and more particularly to the small waste which accumulates at gasworks, and is of little value. The method of use is of considerable importance at present, because, with the increased production of tar and the closing of the Continent to the shipments of pitch, this material is accumulating at most works, and the use of a portion to assist in converting the unmarketable coke into a fuel of the selling value of $3.00 per ton is a double economy. In his recent Harvard lecture on "Coal and its Economic Utilization," delivered before the Royal Society of Arts, Professor Brame gave an account of a coke briquetting plant installed at Smethwick Gasworks over a year ago, which has proved very satisfactory. In manufacture the coke dust is graded to pass a ¼-inch mesh sieve, and is mixed with 8 per cent. of pitch, this mixture being fed to the disintegrator. In the heater a little tar is added, and the hot mass briquetted at 6 tons pressure.

At Smethwick the plant relieves the works of about one-sixth of the pitch made. If then coke breeze were also briquetted, one-third of the pitch could be utilised. The briquettes are suitable for closed stoves, ranges, etc., and form the only boiler fuel used at the works. For the usual open grate the draught is insufficient to burn them without a proportion of ordinary coal.

INEXPENSIVE OIL FILTER

By J. Haliburton

CONSERVATION is an essential factor in every line of industry, and nowhere is this more pronounced than in the power plants of the country. Waste under existing conditions is next to criminal, and it is a commendable feature to not only



OIL FILTER USING STOCKING LEG.

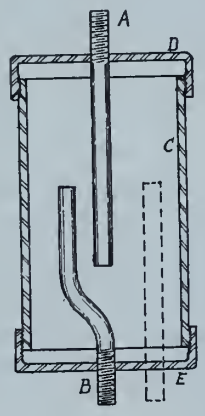
eliminate all waste but to utilize to the utmost all available material so as to maintain the maximum efficiency is service and economy. The accompanying cut illustrates a very serviceable yet inexpensive strainer or filter for cylinder

oil. This consists of a discarded teapot fitted with a portion of a close woven stocking leg. The short piece was sewn across one end and the open end placed over the top of the teapot body, the end of the fabric being provided with an elastic band or other means of securing it to the outer surface of the vessel; a groove similar to that shown offering an excellent facility for securing same. The loose end of the stocking leg is then allowed to sag down into the teapot to form a filtering pocket into which the oil is poured and thereby strained before it passes into the interior of the teapot, from which it is afterwards used by pouring from the spout in the ordinary manner. To prevent the flange of the lid cutting the fabric, it is either removed or given an inward curl.

TRAP FOR STEAM PRESSURE GAUGE

By John Thorn.

THE trap shown can be made with a 1¼-in. nipple C, and two caps D, E. The caps are drilled and threaded to take the two ¼-in. pipes A, B. A straight pipe can be used instead of the bent pipe B, as shown by the dotted lines if desired. It is quite difficult to make the bent circle usually employed in service if a neat job



TRAP FOR STEAM PRESSURE GAUGE.

is desired. The trap shown makes a neat job and if any small amount of dirt gets into the ½-in. pipe B, from the boiler it will settle in the bottom of the trap. The writer has some doubt as to its reliability as he thought that entrapped air might cause the indicating hand on the gauge to vibrate. After a try out this doubt was dispelled.

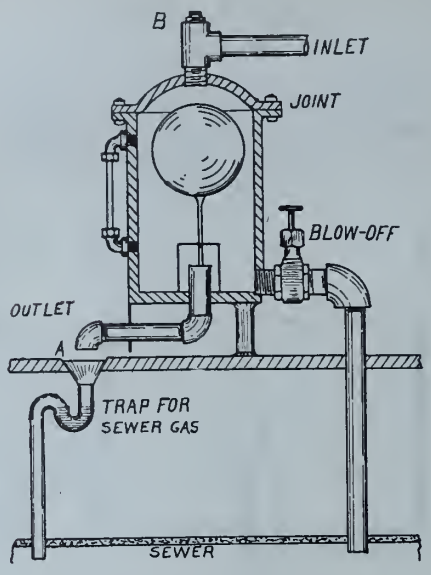
Injury is sometimes done to gauges by the drip cock being left open allowing steam to enter the gage spring.

It is obvious that this can not occur with the trap shown.

INSTALLING GREASE TRAPS FOR SEPARATOR DRIPS

By J. E. N.

FREQUENTLY an ordinary steam trap is connected to the drips from oil seperators on the exhaust pipes from steam engines or pumps. If the drips discharge into an open receiver and the oil is collected for use after being filtered, any stoppage in the trap discharge might be noted before any damage was done, that means oil getting into the steam boilers. If the separator drip is connect-



GREASE TRAP DRAINING TO SEWER.

ed to the sewer directly from the trap, considerable oil might reach the boilers, if a stoppage occurred in the trap, before the stoppage was discovered.

When a heavy cylinder oil is used, a stoppage in such steam traps is quite possible and even probable. Of course there may be exceptions, but many of the traps in question, tapped for half inch and three-quarter pipe threads, have discharge holes no longer than ⅛ inch or slightly over this.

If a trap is used it should be a regular grease trap made for the purpose, with large outlet valves. The connections should be along the lines shown in sketch. It will be noted that the drip in this case is connected with the sewer by a funnel and sewer gas trap, the open space at A enabling the operator to see at once any stoppage in the flow from the separators. These traps cost less than the regular steam traps and only operate successfully with low pressure. Of course grease traps of a different design can be bought.

The gage glass usually fitted to these traps, or any other grease trap, should be treated with suspicion; if they are not blown out regularly the cocks are liable to become choked with thick oil. A ¾-inch blow-off pipe should be a part of each grease trap. If a tee with a removable plug (as at B) is installed, the plug can be removed at times and an oil removing solution poured in; this will remove any oil which may have collected and set on the screen around the drip outlet without taking the trap apart at the joint.

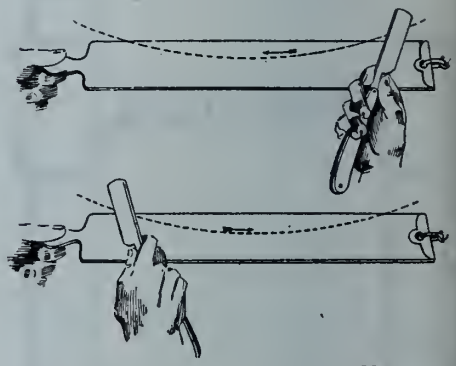
The blow-off can be connected to the sewer as shown, or run to the oil collector. Many dirty boiler jobs could be avoided if more care were taken to install proper grease traps, and to keep them in working condition after being installed.

STROPPING A RAZOR

AT a meeting of hardwaremen in Melbourne recently, the question of how to strop a razor emerged,says Australasian Hardware and Machinery. One man said he had bought about twenty razors in as many years, some of them expensive knives, and was always having trouble. He had come to the conclusion that he couldn't strop a razor properly. Obviously it would be an advantage if every assistant who sells a razor were in a position to tell or show the purchaser how it should be stropped.

The razor is stropped to give it keenness of edge, in reality to clear of foreign matter the microscopic teeth with which the edge is fringed. Hence the desirability of using a suitable strop, a strop with a surface at once "nappy" and soft or pliable. The occasional application of a little olive oil tends to keep the strop in right condition. Even with a good strop, a man may be unable to get his razor right, because his stropping is faulty. The most common mistakes are stropping too heavily and too long. If the razor is in fair order a few passes on the strop, beginning with a slight presure, and ending with almost none, are all that is needed.

Note the position of the hand in the drawing and the direction of travel. The razor should be firmly held, not moved in the fingers, and should always be turned on its back, never on its edge.



RAZOR STROPPING DIAGRAM.

A firm hold of strop and razor and a wrist action of the stropping hand—such are the methods of the expert. If the razor is gripped as shown there will be little, if any, risk of injury to either strop or blade.

The direction, as well as the weight and frequency of the stroke, is of great importance. "Heel to point," it ought to be, but not in a straight line. The curved stroke, experience shows, gives the best results. Rather difficult to accomplish at first, this semi-circular movement of the hand in stropping soon becomes easy enough. It only needs the practice of a few weeks to make it "second nature."

Another important point to remember is that the razor should be laid flat on the strop. The weight of the hand in stropping should really fall on the back of the razor if the rounding and consequent spoiling of the edge is to be avoid-

ed.

Operators' Instruction Course

EDUCATION PAPER—II.

WHAT IS the composition of water?

Theoretically, water is composed of two parts of hydrogen and one part of oxygen, but in practice it includes many other substances, such as lime, magnesia, soda, potash, etc., according to its source.

* * *

What is the composition of air?

Oxygen and nitrogen, in the proportion of 1 to 4, are the principal constituents of air forming the atmosphere. Carbonic acid gas is also present in the proportion of 3 to 4 volumes per 10,000 of air, while industrial conditions influence the amount of other impurities which may assume serious proportions in certain localities.

* * *

What is the composition of coal?

Coal is an impure form of carbon, formed by the decomposition of vegetable growths which existed at one time on the earth's surface. It exists in various qualities, according to its percentage of carbon and volatile matter. Welsh anthracite has over 90 per cent. and lignite about 60 per cent. of carbon, while ash and volatile matter vary from 3 to 30 per cent. respectively.

* * *

How much coal is consumed per horsepower in a large modern power house?

Steam-driven electric plants of large size have operated with as low as 10 lbs. of steam per indicated horse-power, and boiler tests have shown evaporations exceeding 10 lbs. water per lb. of coal, which would result in 1 lb. of coal per horse-power. This is about the low limit for high-class efficiently operated plants, the great majority averaging from 2 to 4 lbs, of coal per horse-power per hour.

* * *

How much water can be evaporated by 1 lb. of the best coal?

The usual value assumed for the best coal obtainable is 14,700 B. t. u. per lb. Divide this by the latent heat of steam and the evaporation from and at 212 deg. is obtained. Thus 14,700÷212= 15.2 lbs. of water. This is never attained in practice, as average run of mine coal has seldom more than 8,000 B. t. u., the results from which are further affected by boiler efficiency. From 7 to 10 lbs. of water per lb. of coal is the usual amount evaporated, under ordinary conditions.

* * *

How much coal per sq. ft. of grate surface can be burned under normal, natural and forced draft?

From 12 to 30 lbs. per hour are the limits from which reasonable efficiency can be obtained with natural draft. Forced draft, either pressure or induced, enables consumptions up to more than 100 lbs. per sq. ft. per hour to be obtained, but with a great drop in efficiency. The highest evaporative efficiency results have all been obtained with a coal consumption at or under 12 lbs. per sq. ft. of grate surface per hour.

* * *

How many B. t. u. does one pound of fair-grade coal contain?

A fair grade of Canadian coal, free from excessive ash, should average 10,000 to 12,000 B. t. u. and selected quality, based on known analysis, from 13,000 to 14,000. Run of mine with excessive ash may not exceed 7,000 B. t. u. per lb.

* * *

What should be the tensile strength of boiler plate?

Modern practice calls for approximately 62,000 lbs. per sq. in. tensile strength in mild steel boiler plate, accompanied by an elongation of 20 per cent. in 8 in. Various bending tests are also specified to insure the proper temper of material.

* * *

What should be the tensile strength of rivets used in boiler construction?

The tensile strength requirements of rivet bars are practically the same as boiler plate, but special allowances are made in boiler design, to provide for them being in shear, instead of tension. The shearing strength of rivet steel is, therefore, taken at 85 per cent. of the tensile strength, and the diameter must not be less than the thickness of the plate.

* * *

What should be the lowest temperature of a furnace when combustion of coal is going on?

The lowest temperature at any time should really be the highest possible for the particular grade and quantity of fuel being used, if efficiency is aimed at. A temperature of 1,400 degs. with fuel consumption of 10 or 12 lbs. per sq. ft. of grate is about the low limit, and with good fuel and combustion should be 1,500. Increased rates of consumption will yield furnace temperatures around 1,800 deg. this being the temperature in the chamber and not in the actual body of the fuel, which is much higher.

* * *

State a rule for finding the size of safety valves for steam boilers?

Safety valve areas are frequently determined with relation to the grate area and the pressure carried, but this method is not satisfactory unless it assumes a maximum rate of fuel consumption. To be correct, a rule for safety valve areas must take into consideration the lift of valve, the heating surface, and the water evaporated. A rule used by some authorities is

$$A = .2074 \times \frac{W\ G}{P}$$

in which A=the area of the safety valve in sq. in.

W= pounds of water evaporated per sq. ft. of grate surface per hour.

P=absolute pressure per sq. in.

G=Grate area in sq. feet.

* * *

Give the principal dimensions of a 60 in. dia. by 14 ft. long horizontal return tubular boiler.

Thickness of shell, ⅜ in.; thickness of head 7/16 in.; length of tubes 13 ft.; number of 3 in. tubes, 82; if 4 in. dia., 50; length of furnace, 5 ft.; weight of boiler about 95,000 lbs. The foregoing thicknesses with double-riveted lap joint represent average practice for 100 lbs. working pressure. If for 150 lbs. pressure, approximately 1/16 should be added to the above thickness.

* * *

What does the horsepower of a boiler depend on?

The power of a boiler depends chiefly on two factors—the area of the grate, and the area of the heating surface. The proportions adopted by makers vary considerably. A ratio of 34.5 to 1 heating surface to grate area is average practice, and assuming an evaporation of 3 lbs. of water per sq. ft. heating surface, the normal power capacity of a boiler would be found by multiplying the sq. ft. of heating surface by 3, and dividing the result by 34.5.

READERS' QUERIES AND ANSWERS

1—What horse-power is required to operate an air compressor with cylinder 16 in. in diameter by 24 in. stroke, discharging at both ends against a pressure of 90 pounds per sq. inch? A belt flywheel, 12 ft. in diameter, is the driving medium, and the revolutions are 100 per minute.—A. R. P.

In order to calculate the required horse-power, it is necessary to know the mean effective pressure and also make

an allowance for friction. Assuming these as 30 lbs. per sq. in. and 20 per cent. respectively, the formula is:

Area of piston in inches, × m. e. p. × piston speed in ft. per min., the whole divided by 33,000, thus for the dimensions given, we have

$$\frac{201 \times 30 \times 400}{33{,}000} = 73$$

20 per cent. of 73=14.6
Total horse-power=87.6

—W. M. McRobert

* * *

2—What is the refrigerating capacity of a double-acting ammonia compressor whose cylinder is 8 in. in diameter and stroke 16 in. when running at 100 r.p.m.? The piston rod diameter is 2 inches.—A. S.

This question is not complete, as suction or back pressure and discharge pressures are not stated, so for convenience the writer has assumed standard conditions of 15.67 lbs. suction and 185 lbs. discharge pressure. The volume of cylinder swept through by piston in one minute equals

$(8 \times 8 \times .7854 \times 2 \times 16 - 2 \times 2 \times .7854 \times 16) \times 100 =$
155823.36 cu. in. =
90.17 cu. ft. per min.

At the pressures given above, it is theoretically necessary to pump 3.83 cu. ft. of ammonia gas per minute to produce 1 ton refrigerating capacity in 24 hours, therefore, capacity of machine equals 90.17 ÷ 3.83 = 23.5 tons. Practically speaking, the capacity would be about 80 per cent. of this or about 18 tons.—S. Balmfirth.

* * *

3—How many tons of work are performed by an ammonia condenser using 300 Imperial gallons at 60 degs. F., the final temperature of which is 90 degs. F.?—A. S.

It is assumed that the quantity of water used is per min. which would give the following result: Total heat absorbed by condenser equals

$300 \times 10 \times (90 - 60) = 90{,}000$ B.t.u. per min.

$90{,}000 \times 60 \times 24 =$
129,600,000 B.t.u. per day.

Since 1 ton of refrigeration equals 288,000 B.t.u., the amount of refrigeration performed equals 129,600,000 ÷ 288,000 = 450 tons.—S. Balmfirth.

* * *

4—How many tons of work result from pumping 160 U. S. gallons of brine per minute through a brine cooler? The temperatures of the ingoing and outgoing brine are 15 degs. F. and 35 degs. F. respectively.—A. S.

Assuming a specific gravity of 1.14 for brine, 160 U. S. gallons would weigh

$160 \times 8.345 \times 1.14 = 1522.128$ lbs.

The degrees change in temperature is 35 — 15 = 20, therefore, the total heat absorbed is

$1522.128 \times 20 = 30{,}442.56$ B.t.u.

The total refrigeration performed per day would, therefore, equal

$$\frac{30{,}442.56 \times 60 \times 24}{288{,}000} =$$

152.21 tons per day.

—S. Balmfirth.

* * *

5—The temperature of liquid ammonia is 84 degs. F., and the temperature of brine in the cooler is 2 degs. F. The liquid, in order to evaporate, must first be cooled from 84 degs. F. to 8 degs. F. The cooling takes place right behind the expansion valve, where part of the liquid evaporates and extracts the heat from the remaining liquid. What is the percentage of loss due to cooling the liquid? The latent heat of the liquid at 80 degs. F. is 560.5 B.t.u.—A. S.

In cooling the liquid from 84 degs. to 8 deg. the drop in temperature is 72 deg. The specific heat of the liquid is 1.1214, which, multiplied by 72, equals 80.74 B.t.u. loss.

The percentage of loss is, therefore, equal to

$$\frac{80.74 \times 100}{560.5} = 144$$

—S. Balmfirth.

* * *

6—A suction pipe, not insulated, passes through a room whose temperature is 60 degs. F. As the pipe must be frosted to deliver saturated gas, a loss is the result. How many B.t.u. are so lost in condensing and freezing one pound of moisture on the pipe?—A. S.

The total B.t.u. lost per lb. of moisture frozen on the pipe may be calculated thus: latent heat extracted in condensing, 966.7 B.t.u.; to cool from 60 deg. to 32 deg. = 28 B.t.u.; latent heat extracted in freezing, 144 B.t.u.; total, 1,138.7 B.t.u.—S. Balmfirth.

ROPE DRIVING

THE rope drive as a power transmission factor has not lost any of its hold in the estimation of those who have made a careful study of its operation. Aside from the question of superlative merit of either the English or American systems, there is undoubtedly a field of usefulness in which it equals and possibly excels other methods.

Regarding the two types of rope generally used—namely, three-strand and four-strand—the former can be made more pliable than the latter, and it is also stronger; but these advantages are more than counterbalanced in the four-strand rope, because compared with the three-strand, it stretches very much less, and has a larger surface in contact with the pulley grooves. It is also capable of a stronger splice. A well-made four-strand rope is, moreover, nearly as strong as a three-strand. but it requires more skill to splice it. The general opinion, now, is that cotton is the best material to use for driving-ropes, and Egyptian cotton, though a little more expensive than American, is generally preferred.

Screenings

Willis—"Bump has a very up-to-date office."

Gillis—"Yes. He has one of these office systems where you can find just what you want when you don't want it by looking where it wouldn't be if you did want it."

Mrs. Casey—"Me sister writes me that every bottle in that box we sent her was broken. Are ye sure yez printed 'This side up, with care on it!'"

Casey—"Oi am. An' for fear they shouldn't see it on the top. Oi printed on the bottom as well."

Did Not Wish To Offend—"John," said Mrs. Mellen to her man servant, "Can you find out, without asking the cook, whether the tinned salmon was all eaten last night? You see, I don't wish to ask her, because she may have eaten it, and then she would feel uncomfortable."

"If you please, ma'am," replied the man, "the new cook has eaten the tinned salmon, and if you was to say anything to her you couldn't make her feel any more uncomfortable than she is.

Sandy McNab, being a popular and well-known member of the village kirk, was asked by the minister to canvass the other members on behalf of a war charity he was interested in.

Soon afterwards the minister met Sandy walking irresolutely along the road, and at once guessed the cause.

"Man, Sandy," he said earnestly, "I'm sorry to see you in this state."

"Ah, weel, it's for the good of the cause," replied the deliquent quite happily. "You see, meenister, it's through these subscreeptions. I've been down the glen collectin' fun's, an' at every hoose they made me hae a wee drappie."

"Every house! But—but—but surely Sandy, there are some of the kirk members who are teetotallers?"

"Aye, there are; but I wrote tae those."

The man stammered painfully as he stood in the dock at the police court. His name was Sissons, and it was very difficult to pronounce.

He had had the misfortune to stay out late and make an uproar the previous night, so that he had to account for it before the magistrate next morning.

"What is your name?" asked the magistrate.

Sissons began to reply.

"Sss-s--s---s---"——

"Stop that noise and tell me your name," said the magistrate testily.

"Sss-sss-sss-ss"——

"That will do," growled the magistrate severely. "Constable, what is this man charged with?"

"Yer worship, I think he's charged with sodywather," replied the policeman earnestly.

Steam Power Plant Auxiliaries

FEED-PUMP GOVERNORS

THE development of governing devices, whereby the speed of boiler-feed pumps is automatically varied to suit changing conditions, is the final step in the elimination of the personal element in the control of boiler feeding plant. The various types of regulators described in previous articles have, as their prime function, the opening and closing of an individual control valve on the feed pipe of each boiler so that the necessary amount of feed water is admitted as required. They are operated directly through variations of water level and are entirely independent of the pressure at which the boiler may be working, and it is this question of boiler pressure, the variations thereof, and the closing of the feed control valve by the regulator which have combined to stimulate the development of pump governors.

Assuming the case of a large battery of boilers on which there was a more or less constant load, a central feed-pump installation might be under constant operation with very little variation in speed due to the steady demand for feed water from the boilers as a whole,—while one boiler might be unloaded due to cleaning fires, etc., another might be taking on extra load and so balancing operations that while their individual feed regulators were in active use, their combined effect on the pump speed would be almost unnoticeable, and close attention by the operators could quite well dispense with a pump governor if such attention could be relied on. The use of a pump governor however not only removes the "if," but insures a closer degree of uniform delivery pressure by the pump than is possible by any hand control.

Excess Pressure

In order to force water into a boiler, the feed pump must have sufficient steam capacity in the cylinders to insure a reasonable excess of pressure in the feed pipe over that of the boiler, say from 5 to 15 lbs. per square inch or more. This excess extends from the discharge side of the pump plunger or piston to the point in the pipe where the feed-regulator is attached, and decreases slightly as it approaches the boiler. When the feed-regulator opens up the control valve, less resistance is offered to the passage of the water, consequently the pump operates at an increased speed. When the regulator causes the control valve to close down some, the reduced area causes the delivery pressure of the pump to increase, until, when it is shut tight, the pressure at the pump will assume the maximum obtainable with the available steam pressure.

Such conditions, of course, are not at all beneficial to the pump and piping, consequently various devices have been invented to vary the speed of the pump according as the control valve on the feed pipe allows more or less water to pass, the pressure of the water being always kept at a higher point than that of the boiler. The principle of operation is therefor based on the difference between the boiler pressure and the pump delivery pressure. Increased demands for feed water mean a reduction of this difference, while the absence of demand results in an increased difference. The available pressure due to this difference is utilized to automatically control the supply of steam to the pump so as to dispense entirely with hand regulation even to the point of stopping and starting the pump.

Pistons, diaphragms, weights, and springs, are variously combined to obtain the desired result, the discharge pressure of the pump being piped to one side of the operating element, while the other side is either exposed to boiler steam pressure, or counterbalanced in a suitable manner permitting of adjustment.

Fulton Pump Governor

This design of governor employs an adjustable counterweight for determining the amount of excess pressure carried and is arranged so that the piston or diaphragm carries boiler pressure on one side and pump discharge pressure on the other, thus requiring the counterweight to balance only the difference between the two, which, at 10 lbs. per square inch involves only a small size counterweight. Both piston and diaphragm types are made, as illustrated in Figs. 1 and 2. The external appearance is slightly different, while internally they are identical so far as the steam controlling mechanism is concerned.

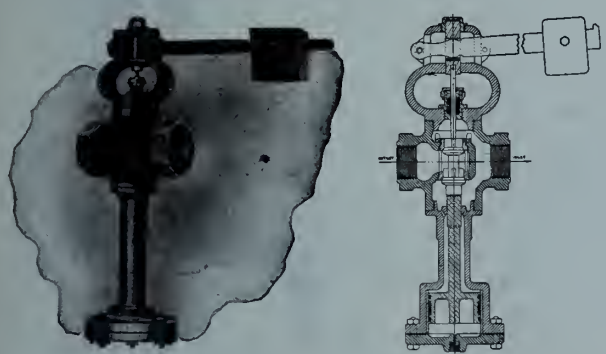


FIG. 1. PISTON TYPE OF "FULTON" GOVERNOR.

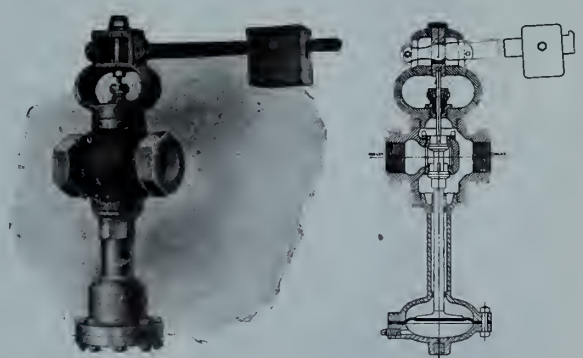

FIG. 2. DIAPHRAGM TYPE OF "FULTON" GOVERNOR.

The piston type, Fig. 1, has a small cylinder formed at its lower end, in which works a metallic piston connected by a rod to the double heat steam valve on the underside of the valve seats. Extending upwards from the valve, through a packing gland, is a spindle, the upper end of which engages with a horizontal lever carrying an adjustable counterweight. Steam from the boiler enters by the inlet, and obtains access to the upper side of the piston through small holes provided for that purpose. The lower side of the piston is connected by a small pipe to the pump discharge, while the steam outlet is connected to the pump steam chest.

Assuming that the excess of pressure desired in the feed pipe is 10 lbs. per

that in order to close the double beat valve the water pressure below the piston must be that much higher than the steam pressure. The excess pressure, of course, can be varied to suit individual requirements, but when once set will remain constant no matter how much variation may take place in the steam pressure of the boiler.

The diaphragm type, Fig. 2, has a flexible diaphragm of suitable material substituted for the piston, and operates against a flattened end of the piston rod. The spaces surrounding the rod down to the diaphragm are also connected to the steam space above, provision being made

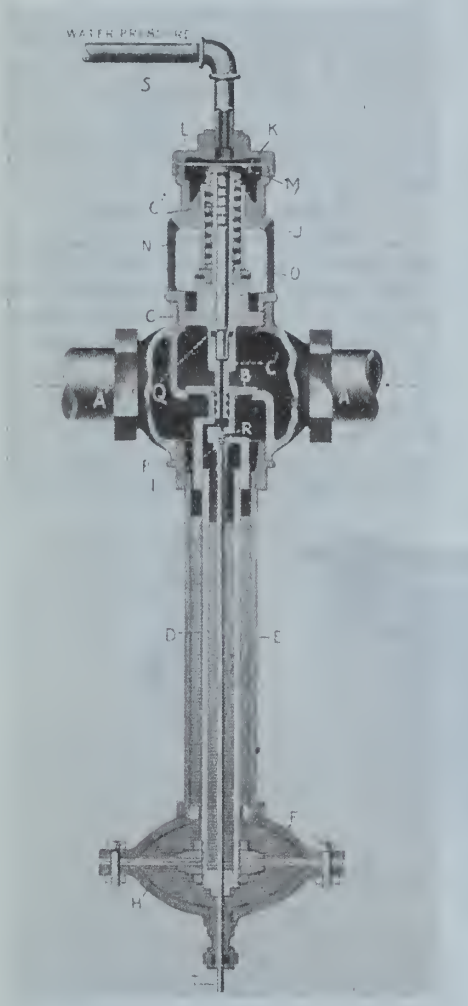

FIG. 3.—SECTIONAL VIEW OF "LOCKE" PUMP GOVERNOR, SHOWING PILOT VALVE AND DIAPHRAGM ARRANGEMENT.

to cover the upper side of the diaphragm with water to avoid damage to the material from the steam heat. In the manner of installation and operation, this type is exactly similar to Fig. 1, both of these devices being the product of the Chaplin-Fulton Mfg. Co., Pittsburgh, Pa.

Locke Pump Governor

This governor is designed for close accurate work in which the water pressure is required to be maintained at a definite point. The construction is rather different from the majority of governors and involves the use of a single beat valuve, a spring-controlled pilot valve operated by the water pressure, and a diaphragm operated by the steam pressure. Fig. 3 shows a section of the apparatus, by referring to which the working will be clearly understood.

Boiler steam enters at A on right as shown by arrow. Water pressure from pump discharge is piped through S onto top of diaphragm L, and at maximum pressure forces down the spring below it which is adjustable by means of sleeve O. In forcing down the spring it causes a small stem to close a valve Q in the bushing C. The lower end of this bushing is a steam tight fit in the centre of main valve B, which moves vertically on this part as shown. Valve B is of hollow construction, carried on the upper end of a tube which in turn is fastened by its lower end to diaphragm H. Under working conditions the spaces in and around this tube are filled with water, the inner body of water being connected with the water below the diaphragm. A small central spindle T enables exhaust valve R to be regulated to the small amount necessary for successful operation.

Assuming the parts to be in position as shown, i.e., steam shut off, and no water pressure—when steam enters through A it presses valve B tightly on its seat, and passes through pilot valve Q down into the central water column, causing the pressure below the diaphragm to increase and force it up so that the tube lifts valve B off its seat and allows steam to pass through to the pump. The two columns of water are now balanced and keep valve B open. Meanwhile, the pump discharge pressure is building up until the water pressure, operating against the adjusting spring, forces down the pilot valve and stops the passage of steam through the central passage to the inner water column. The exhaust valve R allows this pressure to drop to that of the outgoing steam and thus equalizes the pressure on both sides of the diaphragm. When this takes place, the steam passing through closes valve B and stops the pump.

When the water pressure falls again, the spring N lifts up the pilot valve and allows steam to pass to the central water column and open up the main valve again. The governor therefore will allow steam to pass to the pump whenever the water pressure is less than that required to balance spring N. The action of the exhaust valve R is adjusted by turning spindle T to right or left. This governor is one of several types built by the Locke Regulator Co., Salem, Mass., which includes spring and weight adjusted apparatus for a variety of purposes.

S-C Pump Governors

The use of a flexible diaphragm operating against an adjustable spring so that the mechanism will respond to minute variations of feed pressure is a feature of this governor. The fact that the operation of the valve is spring controlled enables the governor to start and stop gradually instead of working at full open or full closed positions only. square inch, the counterweight is set so It is thus capable of varying the pump speed by small increments to suit similar variations in the demand for feed water as happens when a continuous graduated feed water regulator controls the supply to the boiler.

A sectional drawing of this device is shown in Fig. 4. A double seated valve R is carried on the end of valve stem T which extends through spring case I to diaphragm H. By means of screw L and yoke M, the compression of spring K is varied, so that when the desired pressure is attained by the feed water on the other side of the diaphragm, valve R is in closed position. Spring case I completely encloses the parts so that the only packed joint is at N where the ad-

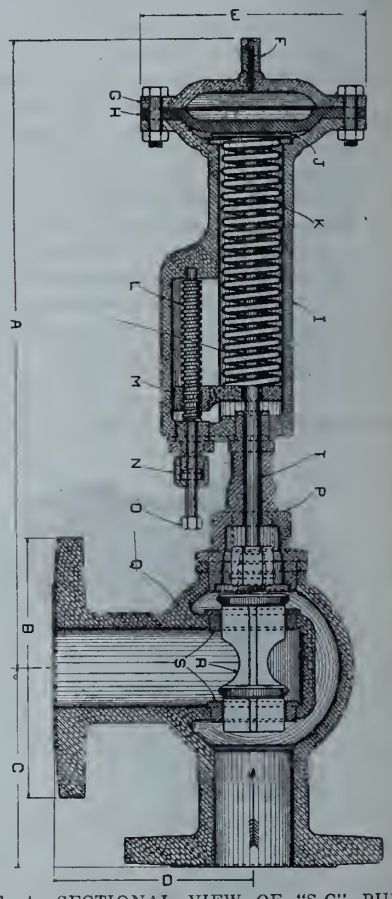

FIG. 4.—SECTIONAL VIEW OF "S-C" PUMP GOVERNOR, SHOWING ADJUSTING SCREW FOR REGULATING MAIN SPRING.

justing screw passes through. As this part is only used when changing adjustment it will be seen there is an entire absence of friction other than that due to the weight of the parts.

When in operation, the spring case is filled with water of condensation and the steam pressure is exerted on this continuously so that the spring has only the excess pressure to balance. When this pressure drops, the valve R is opened to suit the amount of drop,—when more or less water is being used, the governor never shuts off, but floats with the demand and maintains the desired excess water pressure above that of the steam, regardless of the demand and will change the steam supply immediately.

This governor is built by the S-C Regulator Co., Fostoria, O.

Projects and Developments

TRADE GOSSIP

Arthur Vincent, C.E., has been appointed town engineer of Longeuil, P.Q., in succession to the late F. Barbeau.

Courtney, B.C.—The new general store of the Comox Co-operative Society has been equipped with a 1-ton "Armstrong" refrigerating plant.

St. John's, Que.—The Laurin & Leitch Construction Co., Montreal, have the general contract for pumping and filtration plant for the Town Council.

Tecumseh, Ont.—J. R. Sculland, of Windsor, has the contract for reinforced concrete water tower and basin costing $6,500 for the Eau Claire Waterworks Co.

Vancouver, B.C.—Howard's chocolate factory has been equipped with a ½-ton refrigerating machine, furnished by the Armstrong Machinery Co., Spokane, Wash.

Port Arthur, Ont.—The Canadian General Electric Co. has secured the contract for the sub-station and electrical equipment for the Eastern Terminal Elevator.

Cornwall, Ont.—The Cornwall Dairy Co. have established a new creamery and dairy, and have built cold storage rooms in connection with same. They will install a refrigerating plant.

Swanson Bay, B.C.—A 3-ton refrigerating plant, furnished by the Armstrong Machinery Co., Spokane, Wash., has been installed on the premises of the Empire Pulp & Paper Co., at Swanson Bay.

McLeod, Alta.—The meat market of P. Burns & Co., at McLeod, has been remodeled and equipped with a 1-ton refrigerating plant, furnished by the Armstrong Machinery Co., Spokane, Wash.

Montreal, Que.—It is expected that the Montreal Tramways Co.'s new steam plant will be in operation in a few weeks. This plant has a capacity of 12,000 k.w.h., or of about 17,000 h.p., developed from steam turbine, and a similar installation will be added next year, making a total of 34,000 h.p.

Hydro Commission Takes Over Power Co.—The Hydro-Electric Commission on Aug. 2, formally acquired the plant of the Ontario Power Co., the largest and most efficient developing plant on the Canadian side of the Niagara River. This plant was purchased some months ago by the Commission for $22,000,000, and it will form an important link in the Chippawa Creek development scheme, the ultimate capacity of which will be 900,000 horse-power.

Roland C. Harris, Commissioner of Works for the City of Toronto, has been appointed to act, in an honorary capacity, as Fuel Commissioner for the Province of Ontario, in association with the Federal Fuel Commissioner, C. A. McGrath. Mr. Harris will co-operate with the Federal Commissioner in all matters affecting the fuel situation within the Province of Ontario, and it is understood that his appointment will be ratified by a Dominion Order-in-Council.

James Fulton Cummings, a pioneer electrical engineer, who for many years was associated with the interests controlled by Thomas A. Edison, died on July 27, at Long Beach, N.Y. Mr. Cummings, who was born in London, Ont., 48 years ago, installed the first electric light stations in Philadelphia, Cincinnati and a number of other cities. He then went to Russia, where he worked out the plans by which electric wires in St. Petersburg, as the capital was then called, were placed in underground conduits. He did similar work in London and other English cities. He was considered one of the foremost engineers in that particular line of work.

CATALOGUES

Engine Room Supplies is the title of a booklet recently issued by the Quaker City Rubber Co., Philadelphia, Pa. This booklet is exceptionally complete and comprehensive, and will serve as a useful guide to the engineer in selecting packings, hose and other necessary engine room requirements. The principal lines described include Daniels', P. P. P., rod packing, Ebonite sheet packing, gaskets and steam hose. "Crown" and "Quaker City" packings. The booklet is pocket size and contains 63 pages with index.

Air Compressors. — Bulletin K-500-A, illustrating a line of power driven, single stage, straight line air compressers manufactured by the Canadian Ingersoll-Rand Co. of Montreal. These machines are designed for motor or belt drive and are furnished with a special short belt drive where floor space is a consideration. They are intended for use in industrial and mining plants where units of 950 cu. ft. displacement and under per minute are required. Eighteen sizes are built giving a wide range of choice.

Feed Water Treatment.—The Dearborn Chemical Co., of Canada ,Ltd., Toronto, are distributing a bulletin describing the Dearborn scientific treatmen of boiling feed waters. The bulletin gives a list of the substances commonly held in solution in feed waters and describes their action either in the formation of scale or corrosion of the boiler plates. The bulletin also deals with the Dearborn method and boiler preparations.

Electric Lamps.—Bulletin No. 78 describes the Cooper Hewitt electric lamps for photographic purposes. The bulletin gives full particulars and prices of the various outfits and different apparatus used in connection, accompanied by illustrations. The bulletin also contains suggestions as to the proper outfit to be used for various purposes in photography with illustrations showing studio arrangements. Copies of the bulletin may be obtained from The Cooper Hewitt Electric Co., Hoboken, N.J.

Steam Specialties—The V. D. Anderson Co., Cleveland, Ohio, have issued a new and well gotten up catalogue entitled "Anderson Steam Specialties," which include steam and air traps, steam and oil separators, water columns, pressure oil filters, copper floats, etc. The construction and operation of each product is fully described, accompanied by illustrations showing exterior and cross sectional views. Tables are also included giving the principal dimensions and other data for each size of trap or separator, etc. The catalogue also contains plates showing three arrangements of the Anderson oiling system.

Mechanical Rubber Goods, Valves.—Catalogue and price list No. 8 deals with an interesting line of valves, packings, and mechanical rubber goods manufactured by Jenkins Bros., Ltd., Montreal. This is a useful catalogue to have on file for reference, as it covers a full line of the above products and contains considerable descriptive matter about each in addition to the price lists. The catalogue is fully illustrated, while the concluding section No. 8. contains a price list of parts, tables of weights, and dimensions, together with diagrams, and also provincial registration numbers for the various types of valve. In this section is also included diagrams in connection with the dimension tables. The catalogue contains 252 pages, including a complete index and is bound in substantial cloth covers.

Progress in New Equipment

NEW TYPES OF OIL CIRCUIT BREAKERS

TO its line of type B oil circuit breakers, the Westinghouse Electric & Mfg. Co. of East Pittsburgh, Pa., has added the two types of breakers illustrated. These are designated as type B-2 and B-3; they are for use on alternating current circuits up to 23,000 volts. Type B-2 breakers have a carrying capacity of from 300 to 2,000 amperes; type B-3 of from 300 to 1,200 amperes. Distinctive features of this line are rigidly clamped porcelain pillar bushings, self-cleaning butt brush contacts, auxiliary arcing contacts and spring-accelerated opening. Due to careful design, these are the most compact single-frame breakers produced.

Type B-2 breakers are furnished for panel-mounting, hand operation, or for wall or pipe-frame mounting, electrical operation. Type B-3 breakers are furnished for wall or pipe mounting only, for hand operation through bell cranks, or for electrical operation. For both types, tripping may be either automatic or by hand. Hand-operated breakers are actuated by a handle projecting through a cover-plate on which is mounted the automatic trip coil (if any). When the breaker is electrically operated, the trip coil is mounted on the face of the panel. Remote control breakers operated by bell cranks and rods are provided with a spring to assist the force of gravity in opening. A dashpot brings the moving parts to rest without shock.

When pressure is brought to bear on the main contracts, as the breaker closes, the bent copper leaves of the moving members wipe across the plane stationary contacts, thus ensuring a solid metal-to-metal contact. Arcing contacts consist of a copper-tipped spring plunger mounted on the moving element, which bears on a copper stud on the fixed element.

"MICHELL" THRUST BEARINGS

WITH a view to manufacture in quantity and placing them on the market on the same basis as that on which ball bearings have long been sold, Broome & Wade, of High Wycombe, Berks, England, are now standardizing certain sizes of Michell thrust bearings, says Engineering.

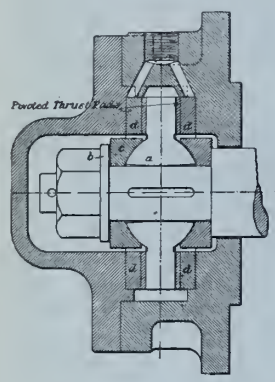

FIG. 1.

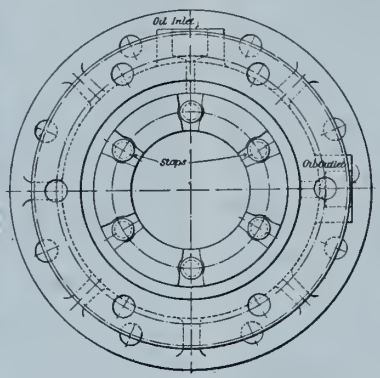

FIG. 2.

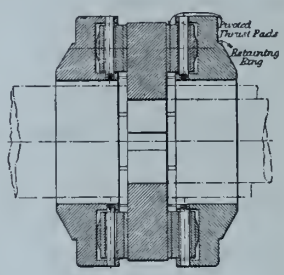

FIG. 3.

MICHELL THRUST BEARING DETAILS.

One form of standardized design is illustrated in Figs. 1 and 2. In this case the thrust collar (a) is bored to a barrel section and instead of being clamped between its spherical seats is loosely held, as is indicated by the space shown between the washer (b) and the opposing face of the seat (c). It is thus capable of taking slight tilts so as to distribute the load equally, in spite of any bending or deflection of the shaft. The collar transmits the thrust to the series of pivoted blocks or pads shown in position at (dd)—of these one set serves to take a thrust and the other a pull. Provision is made, it will be seen, for a continuous supply of oil. This pattern, being entirely enclosed, is suitable for use on pumps, fans or worm gears.

Another form of standardized thrust block is shown in Fig. 3. Here the bearing is not complete in itself, but is designed to fit into seats machined for it in the gear casing or whatever other machine part to which the bearing is to be applied. In this case the blocks are, it will be seen, mounted on two retaining rings. These, when the bearing is mounted in place, fit on bevelled seats, sufficient freedom being allowed to permit of the pressure being fairly distributed over the pads. The rings are prevented from being carried round with the revolving shaft by feathers on the houisng of the machine. This pattern is made in sizes to fit shafts from 1 in. up to 3½ in. in diameter, and to carry loads from 1,000 lb. to 8,000 lb. In this case the pads pivot about a point contact, whilst in the case of the pattern represented in Figs. 1 and 2, which is intended for heavier loads, the pads have line contact with the housing. Both types of bearing can be run at very high speeds, since centrifugal action in no way affects their working. With loads of 400 lb. to 500 lb. per square inch the coefficient of friction is commonly about 0.0015.

A REMARKABLE OIL ENGINE

By H. P. Hoag

IN the issue of this journal for May the writer described a certain device evolved during his experience in adapting a line of gasoline engines to burn kerosene. The engine illustrated in the accompanying sketch however, is a real kerosene engine that will start and run on kerosene and has neither carburetor nor electrical ignition. It is the invention of a Danish engineer, R. M. Hvid, and is bound to revolutionize the internal combustion engine, giving as it does the same economy as the world famed Diesel engine.

For those unfamiliar with the Diesel engine it might be stated that first, it is a high compression engine, combustion

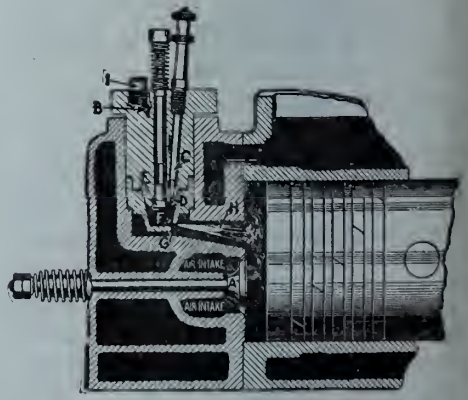

FIG. 1—SECTION OF CYLINDER HEAD SHOWING IGNITION CUP WHICH AUTOMATICALLY FEEDS FUEL TO COMBUSTION CHAMBER.

being caused by the heat of compression which is about 500 lbs. per sq. in., (it being an established engineering principle that a high temperature can be attained by air compression) the resulting

Has Anybody Here Seen Hector?

Has anybody seen Hector at a plant in Missouri, where the engineer had to try to clean the boiler on Sunday because that was the only day it could be spared? Well, the engineer worked all day Sunday and the best he could do with the cleaner he then had was ten tubes per Sunday. The condition of the boiler as to scale kept getting worse and worse. Then Hector was called in.

Hector is a "Bulldog" cleaner and the first day he started chewing off scale, he got 2,000 lbs. from a 300 h.p. Heine Boiler. He cleaned it thoroughly.

Next Sunday the engineer was able to enjoy a well-earned rest.

And you bet he was glad he had thought to call Hector into his plant.

Did anybody see Hector wade through solid closed-up tubes of a B. & W. Boiler in a New York State plant?

Did anybody see him when he ran continuously for 480 hours, removed 6,842 pounds of scale and called for no repairs except drills?

These are the sort of things which Hector is doing all the time.

He's the best little fighter of scale you ever saw. True to his Bulldog nature, Hector never lets go till the tube is clean and shining.

Give Hector a job in your plant.

We have a Catalog which we'll be glad to put in your hands. It describes all Types of Liberty Cleaners. Ask for Catalog H

The BULLDOG Cleaner—for bent tubes—3 and 3¼-in. sizes.

The BULLDOG Cleaner—for straight tubes, 3½ and 4-in. sizes.

Pittsburgh, Pennsylvania

If any advertisement interests you, tear it out now and place with letters to be answered.

temperature being about 1000 deg. Fahr. Nothing but pure air is taken into the cylinder during the suction stroke, then when the piston reaches the highest point of compression, fuel is injected into the cylinder by means of air compressed to about 800 lbs. per sq. in., then cooled. Combustion begins the instant the oil meets the hot air in the cylinder and continues through that part of the working stroke during which fuel is introduced. While the Diesel type gives the very highest economy known to the internal combustion engine, it is never built in small units owing to the expensive apparatus necessary to inject the fuel under such high pressures.

Wonderful as the reliability and fuel economy of the Diesel engine are, the Hvid principle bids fair to outclass the former owing to its extreme simplicity and ease of starting as well as economy, the fuel consumption being half a pound of fuel oil per horse power hour. Another great point of advantage this new type has over the Diesel is that it can be built in small sizes which of course is out of the question with the Diesel type as explained above. Think of an engine, without carburetor batteries, magneto, spark plug, or wires, or the application of any external heat, that will start and run on most any kind of oil, such as kerosene, distillate, fuel oil, or crude oil, in fact any kind of oil that will flow, machine, fish. lard, linseed, olive or peanut oil. This type of engine is now being built by several firms. It was recently the writer's privilege to investigate several of the Hvid type engines now building in the United States both stationary and marine, which proved very interesting indeed.

In this new principle combustion is obtained by the heat of compression as in the Diesel, but the secret of the new system is in the patented fuel cup which times the ignition and represents the only method by which combustion by compression can be easily controlled.

In the sectional view the burning oil can be seen at H, the principle of operation being as follows. During the suction stroke, pure air only enters the cylinder through the intake valve. Oil is admitted by valve E, the quantity being varied by needle valve C, which is under control of the engine governor. As the piston returns and compresses the air to about 450 lbs. per sq. in. the temperature rises to about 950 deg. Fahr. and heats the small fuel cup red hot which brings about a partial combustion of the fuel oil in the bottom of the cup, causing the pressure in the cup to immediately rise above the air pressure in the cylinder which forces the hot oil out through the small pin holes in the cup into the cylinder when it comes into contact with the heated air in the cylinder and burns as shown at H, forcing the piston forward on its power stroke. It will be seen that this new principle incorporated into a substantial design, doing away as it does with all electrical apparatus for igniting the charge, must result in simplicity and reliability and in turn supersede the gasoline engine for at least stationary, portable and marine work.

TYPICAL AUTOMATIC STARTER EQUIPMENT.

AUTOMATIC STARTERS FOR INDUCTION MOTORS

DUE to the unprecedented demand for manufactured products of every kind, industrial plants in all parts of the country are being taxed to their utmost capacity. In addition, the cost of labor and machinery has been increasing at an extremely rapid rate. The magnitude of these factors has forced manufacturers to employ every means available in an effort to increase production or to reduce operating expenses. This may be accomplished by reducing the number of operators, by simplifying the duties of the present operators so that more attention may be devoted to the production of a larger quantity and a higher grade of product, or by furnishing better protection to the apparatus installed, thereby insuring continuity of service.

TYPICAL AUTOMATIC STARTER EQUIPMENT.

One of the factors by which the desired results may be accomplished is the use of automatic starters and controllers for the motor-driven machinery employed. Among the companies producing such control apparatus is the Westinghouse Electric & Mfg. Co., East Pittsburgh, Pa., several of whose starters are shown in the accompanying illustrations. These automatic starters are for use with single phase or polyphase squirrel cage and wound-rotor induction motors, where it is desired to start the motor from a remote point, or where automatic acceleration is required to guard against improper starting by unskilled operators. They are simple, reliable, and rugged in construction, consisting of a magnetic contactor panel and a master switch, which may be either a push button, a float switch, a pressure regulator, or similar device for closing the control circuit, depending upon the service. The vital element is the magnetic contactor. The contactors used on these starters are of a type which has been used by the West-

Can you keep the pointer where it belongs?

It's getting near four o'clock. The demand for power is a trifle heavier than usual. The peak is coming. The sockets click one after another in a steady stream. The demand for steam is going up, up, up. Can You Keep The Pointer Where It Belongs?

Sturtevant
(TRADE MARK)

Turbo-Undergrate Blower

will keep steam up. It supplies all the draft you want and just when you want it.

When you buy a blower be sure it's a Sturtevant. The Sturtevant name is a guarantee of mechanical excellence—a guarantee that you will have no breakdown and no bearing trouble.

The Sturtevant Set has generous bearings with oil rings and large reservoirs. One filling will last for weeks.

To prevent the escape of steam from the casing there is a floating stuffing box. If for any reason through neglect or carelessness this is allowed to leak, there is a special "water-throw" collar which makes it impossible for steam to enter the bearings. Furthermore, the floating stuffing box makes it possible to exhaust against back pressure as high as 25 pounds.

If you have trouble getting enough steam or keeping the needle where it belongs, write us for bulletin No. 214-U.

inghouse Co. with marked success in steel mill, cement plant, and mine installations where the requirements are extremely severe. The contactors are opened by strong spring action, assisted by gravity. The destructive action of the arc is reduced to a minimum by strong blow-out coils and arcing horns.

The operation of the starters is exceeringly simple. When starting motors driving line shafting, wood-working and metal-working tools and similar apparatus, it is only necessary to press a button and close a small knife or snap switch. The starter then automatically makes the proper connections to limit the starting current to a suitable value and to vary the time required for acceleration according to the load on the motor, thus preventing damage to the machinery by too slow or too rapid acceleration, and saving time by bringing the motor to full speed at the most rapid permissible rate.

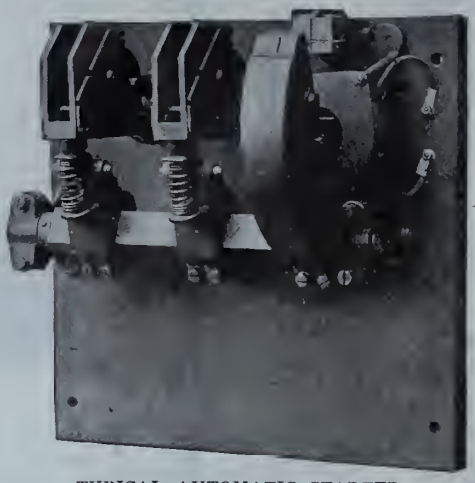
Sole Canadian Representative:

CANADIAN ASBESTOS CO.

Montreal, Que.

When used for pump or compressor service in connection with a float switch or pressure gauge, the action of the starters is entirely automatic, the motors being



TYPICAL AUTOMATIC STARTER EQUIPMENT.

started when the pressure or liquid level of the tank controlled falls to a predetermined point and stopped when the desired maximum pressure or level is reached, or vice versa.

The automatic starters for squirrel cage motors are most frequently employed for starting motors operating centrifugal pumps, air compressors, fans, blowers, metal-working and wood-working machines, and other apparatus requiring starting torque less than full load torque. This type of starter, however, owing to the wide application of squirrel cage motors for industrial service, can be applied economically for starting service in nearly every industry.

Squirrel cage motors of 5 horse-power and smaller are usually connected direct to the line. Large squirrel cage motors are first impressed with low voltage from auto transformers or connected to the line through resistance, so that in

TYPICAL AUTOMATIC STARTER EQUIPMENT.

either case the starting current is reduced. When the speed of the motor has reached such a point that the starting current has decreased sufficiently the motor is then automatically connected to the line.

The automatic starters for wound rotor motors are particularly adaptable for starting motors driving plunger pumps, positive pressure blowers, air compressors, long line shafts, and loads having heavy inertia. The severe starting conditions encountered in this class of service require from 100 to 200 per cent. full load torque in starting, making automatic starting a very desirable feature.

When an automatic starter is used in connection with a wound-rotor motor, the line switch is first closed, with the maximum resistance in the rotor circuit. When the speed falls to a predetermined value, a relay closes a magnetic contactor, which cuts out a part of the resistance in the rotor circuit. Each contactor operates in a similar manner, cutting out its portion of the resistance at the proper time until all the resistance is short circuited by the last contactor.

The power on any circuit may fail suddenly; therefore, it is important that

TYPICAL AUTOMATIC STARTER EQUIPMENT.

some protection be afforded both operator and motor against an unforeseen return of power. This protection may be provided for motors, operating pumps, compressors, etc., by a low-voltage release to disconnect the motor from the line when the voltage is low or power fails entirely; then, as soon as power returns, the motor will automatically start up again. In many applications, however, such as for motors operating metal-working or wood-working machine tools, low voltage protection is required. Motors so protected are disconnected from the line when power fails, and will not start when power comes on again until the operator presses a button or there is no danger from the unexpected starting of a machine.

The advantages resulting from the use of automatic starters for induction motors comprise: absolute protection to both operator and expensive machinery, proper starting at the most rapid permissible rate, economy in operation and maintenance, convenience of remote control, and automatic operation.

Almost every manufacturing process has a certain known temperature at which the best results are produced.

Large sums have been spent experimenting to find this efficient temperature and costly machines and equipment have been installed endeavoring to accurately maintain a proper temperature throughout the manufacturing operation.

Some depend on the thermometer and human intelligence. Others use complicated, indirect-acting apparatus operated by auxiliary power such as electricity, water or compressed air. The most modern and reliable method is to use the

SARCO TEMPERATURE REGULATOR

This regulator is entirely automatic—operating by hydraulic pressure created within itself. It is highly efficient for accurate temperature regulation in tanks or rooms. Quickly and easily installed and requires no auxiliary assistance or attention of any sort.

This regulator follows the fluctuations of the working load and saves the heating or cooling medium. It is small in size and cost; increases the quality of product and reduces operating expenses.

WM B SCAIFE & SONS CO PITTSBURGH PA

You see Jefferson is like any good Union up to this point—but

Well, let's go back a bit first—What is it that you engineers have been looking for in a pipe union? Isn't it extraordinary strength that you may make a connection anywhere, above ground or below, and know that whatever happens it's going to stay tight—and yet come off when you want it off, without somebody breaking their back doing it.

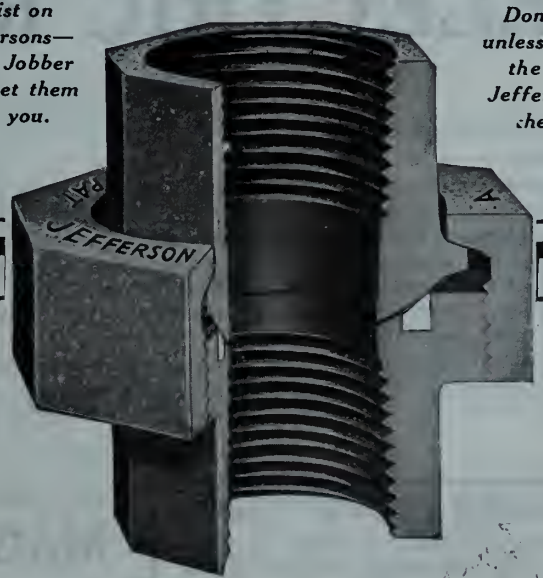
Jefferson Unions

are heavy—the heaviest of their class made. The castings that they are made of are tough. I don't believe there's a wrench made that can chew up their pipe ends or stretch their threads so as to impair their efficiency. Then the threads are coarse and are accurately and deeply cut so the union will set up quickly. So far, the Jefferson is no better than any good honestly-made pipe union—but it's the way that the seat is ground and the seat ring inserted that makes it **distinctly different.** In the first place the seat is ball shaped—it must set up perfectly tight—then the ring is a piece of solid brass tubing which is forced into a recess back from the runway—the joint can't corrode and it can't work loose. But thus—the book I'm holding to mail you tells the whole story. Write for it to-day.

The Jefferson Union Company

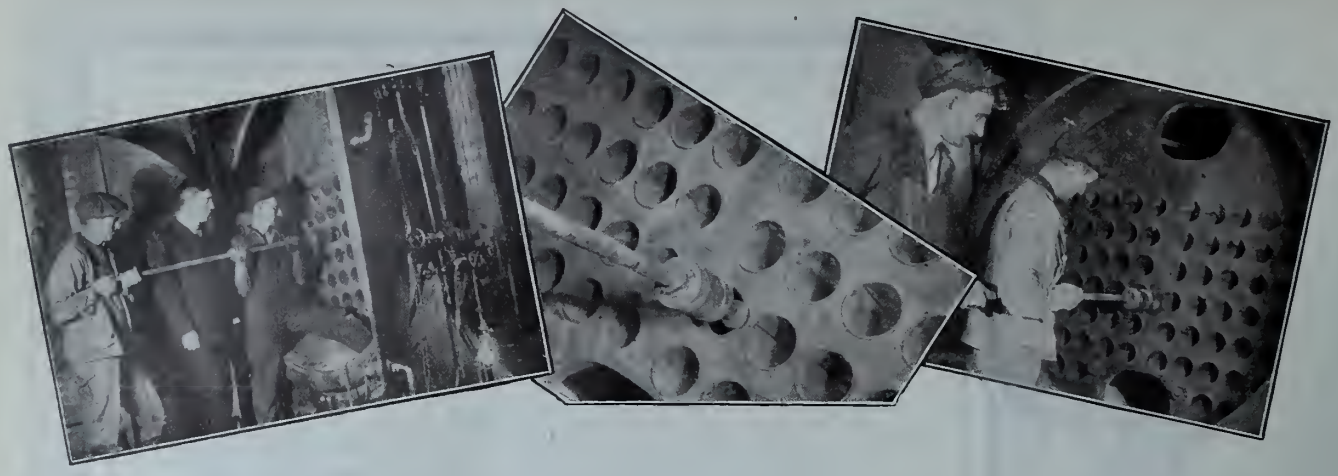
Lexington - - Massachusetts

Insist on Jeffersons—your Jobber will get them for you.



Don't buy unless you see the name Jefferson on the nut.

If any advertisement interests you, tear it out now and place with letters to be answered.



There are many skeptical engineers who won't believe an advertisement, but who will accept the result of an actual demonstration.

We say to those men: "We don't ask you to believe us when we claim, month after month, that the **Dean Boiler Tube Cleaner** will remove scale from your tubes more **thoroughly** than any tool you have ever used.

"We simply ask you to let the **Dean** itself show you what it can do. Give it a trial at our expense. Then, if it doesn't live up to every claim we have made for it, ship it back, and we lose."

To secure the details of our liberal offer, address any of the offices below. Ask for Booklet "Logic of the Dean."

FOR ELECTRIC RAILWAYS

LONDON & LAKE ERIE RAILWAY.

The Magnolia Metal Company. London, Ont., Oct. 6th, 1916.

Gentlemen:—

It affords me much pleasure to testify to the merits of your product.

Have used it continually for four years, and, as stated to your Mr. Peck, found it most satisfactory, both as to quality and service.

We have not in the period named had a single hot journal or bearing, and as our cars run at times over 40 miles per hour, we think this is a record.

One thing is certain, if the man who uses the metal does his work properly, no fear may be entertained that it will fail.

I have no hesitation in giving you this testimonial, which is deserved.

Yours truly,
W. N. WARBURTON,
General Manager.

Garlock High-Pressure Piston Rod Packing

Style No. 200.

Is built up on a core consisting of several flattened tubes.

The tubes are braided from the highest grade of asbestos yarn, and are cemented together with the best rubber friction.

The tubes are cemented only on the outside, therefore the packing is lighter per linear foot than other types of high-pressure packing.

In service the tubes open under pressure and expand the packing against the piston rod.

The core of flattened tubes is backed with a cushion of high-grade rubber, so compounded as to retain its resiliency under heat.

The tube-core and rubber cushions are covered with cloth woven from the highest grade of long fibre asbestos.

Our high-pressure packing is not merely smeared on the outside with graphite and grease.

Every fibre of it is saturated with a specially prepared lubricant, which does not affect the rubber cushion or friction.

The outside of the packing is coated with the best grade of floating stock graphite.

The best materials we can buy are used in the manufacture of our high-pressure packing.

It is built up in rectangular form and uniform shape and exact sizes are thereby obtained.

Asbestos packing, which is rolled around a rubber core and afterwards distorted by running through a square die, does not retain its shape or size.

Our high-pressure packing is made by experts who have done nothing else for years but make that one type of packing.

The length of service obtained from it is greater than that secured from other makes, therefore the labor cost of applying and adjusting is less.

Our packings are sold at net weights; weights of tubes and boxes are not included.

Every pound of our high-pressure packing carries with it the Garlock guarantee of satisfactory and economical service.

We will promptly replace or refund the cost of any of our packings which may prove unsatisfactory to our customers.

Plibrico — Endorsed by some of the leading Engineers as the Greatest Furnace Lining of Recent Times

PLIBRICO—makes a solid one-piece lining without joints. Absolutely gas and air-tight. Saves its cost in fuel in a month or two—you will have a steady fire with less effort and less coal by using it.

PLIBRICO—is mixed ready for use, requires only half the time to install and does not require skilled labor. Any laborer who is at all familiar with the building line can use it. DOES NOT BREAK, CRACK OR SHELL OFF LIKE ORDINARY BRICK.

Can be used for front door arches, side walls, bridge walls, combustion chamber and rear arches. A highly refractory, plastic, one-piece furnace lining for boilers, baffles, Dutch oven construction, cupolas, retorts, enamelling furnaces, gas and oil-fired furnaces, and wherever a high-grade fire brick is required. Sets quickly—after a few hours with a low fire to draw off the moisture, you may fire up as usual. No special forms required.

Ideal for temporary repairs. Better order a barrel and have it ready for an emergency.

PLIBRICO BOND—A high temperature cement for repairs

"PLIBRICO BOND" is a product which gives a perfect bond between fire-brick, and does not allow the fire to burn out the joints, as is the case where fire-clay is used. Prevents furnace walls from cracking and crumbling.

It's the most practical and logical high temperature mortar you can use. It's the ever-ready repair cement that you should have in case of emergency.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

Instal now a positive preventive of high and low water troubles

The Vigilant Feed Water Regulator, by keeping the water level within ¼" of middle gauge, gives you this absolute protection. And besides this, the middle gauge means efficient steaming with reduced boiler repairs and fuel saving of 3 to 17% (by actual record).

Don't continue to take chances with the old hand-regulated method, instal the Vigilant now.

GAUGES

How Do!!

To-day I am going to talk GAUGES

Do you know we handle the most complete line of gauges imaginable? Yes! it's a fact. Every type of Gauge for measuring any pressure, vacuum or draft. Also Gauge Testers. But here's the line in a nutshell.

Steam Gauges, Vacuum Gauges, Ammonia Gauges, Mercurial Barometer, Gauge Testers, Test Gauges, U Gauges, Mercury Pressure and Vacuum Gauges, "Redline" Differential Draft Gauges.

Keep this in mind when in the market or, better still, get our Catalog Sections P.H. 1-50-75-for your file. Good-bye; see you next month.

D. K. McLaren's Belting

Used by Leading Power House Plants

MORE POWER

Discard Ordinary Belting and Use D. K. McLaren's

Belting that repeatedly breaks, stretches and fails to grip the pulley every minute of the day is ordinary belting. It's losing you money in lost power and lost power is very expensive in these days of advancing fuel prices.

To make certain of getting the most for your money you should use McLaren's Belting. With it you are assured of every bit of power.

There's not a leather belt that will not slip a little, also break at some time, BUT with D. K. McLaren's belting you get a minimum amount of slipping and fewest number of breaks.

Our highly scientific method of manufacturing is the secret of our belt excellence. It includes the famous—

British Oak Tanning Process

This method, coupled with the selection of the best hide-centres, gives the leather mighty strength and durability.

Look for "Oak Leaf" Trade Mark on all our belting.

The Double Floating Head eliminates the danger of expansion strains; they are in sections so as to differentiate between expanding and contracting of tubes of different temperatures.

The Helical Spiral Corrugation gives the water a whirl, keeping tubes clean and free from scale. By this method a gain of 50% in heat units is made.

Corrugated Copper Tubes eliminate formation of scale and prevent splitting (common in brass tubes).

Plants of all sizes are finding the Alberger a daily economizer and efficiency promoting heater. Full details will gladly be given upon request by our agents or ourselves.

SKF

Repeat Orders—The Acid Test

Repeat orders are the acid test of a product. No man buys a second time unless he has found a satisfactory product.

In September, 1915, the Colt's Patent Fire Arms Manufacturing Company bought 50 SKF Ball Bearing Hangers—as a trial installation. After a year's trial they bought 400 additional SKF Hangers.

But this is not all. In January, 1917, they bought 200, and in May, 1917, about 500 SKF Hangers, making a total of over 1,000 SKF Hangers.

This is satisfaction—SKF satisfaction—and repeat orders are the proof. Our Hanger Catalog No. 78 will give you further proof. Send for it.

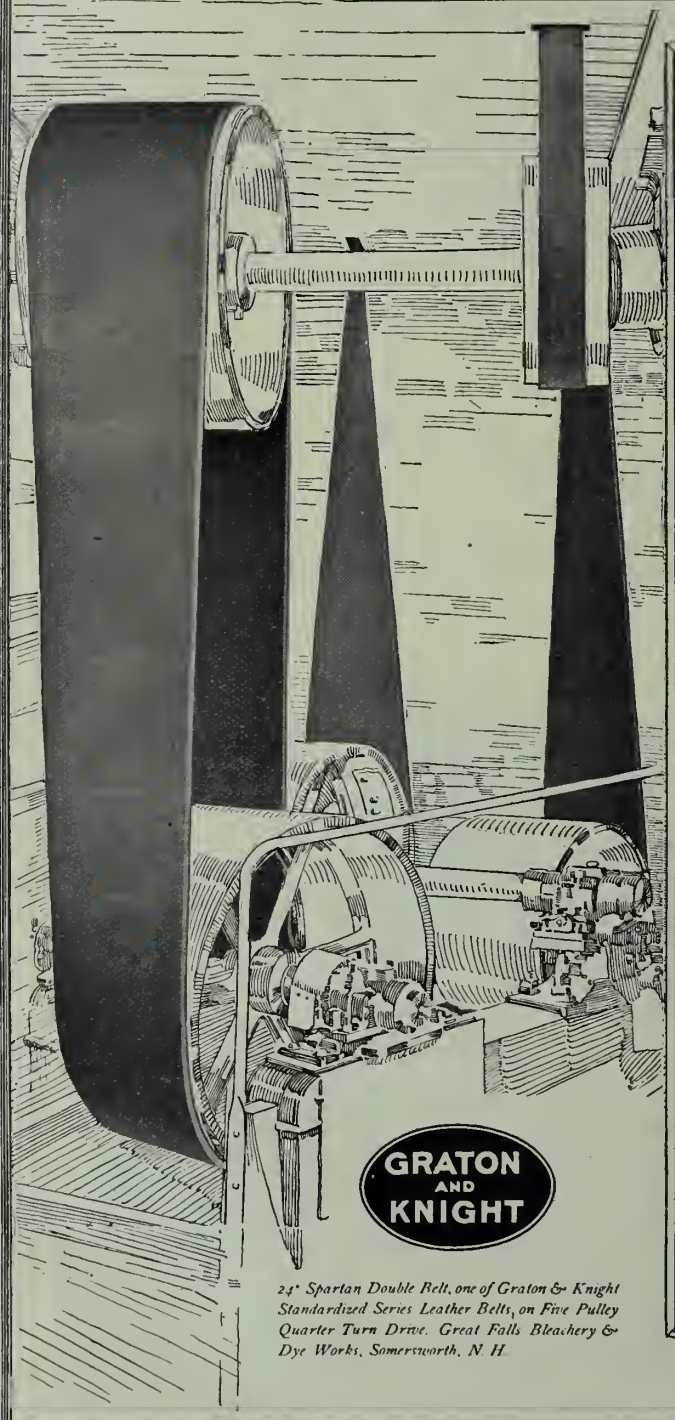
GRATON & KNIGHT

Standardized Series LEATHER BELTING

Tanned by us for belting use



24" Spartan Double Belt, one of Graton & Knight Standardized Series Leather Belts, on Five Pulley Quarter Turn Drive. Great Falls Bleachery & Dye Works, Somersworth, N. H.

It Begins in the Tannery

Leather is the Standard Belting Material

To us, the largest belting makers in the world, every possible belting material lies open for selection and use. But the belting experience of generations points to the unescapable fact that leather has the properties necessary to make good belting.

Leather that is properly tanned for belting is tough, flexible, durable and prehensile. It preserves the natural softness and mobility of the skin, ensuring an effective grip on the pulley surface.

We have standardized these requirements of perfectly tanned belt leather. The standard in each case is the highest *working* efficiency in the finished belt.

Since the market cannot supply tanned belt leather that continuously measures up to Graton & Knight Standards, we tan our own hides. Last year, we tanned 285,000 of them, in our own tannery. We tanned them for *belts*. We tanned them to definite and uniform standards of belting requirements.

This standardization of material is the foundation of Graton & Knight quality.

It makes the Standardization of Graton & Knight Belts an actual, practical thing.

Think what other standardized products have done for you—and consider the standardization of belting on that basis. Let us send you complete information on the subject.

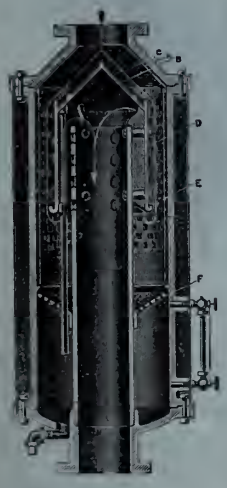
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Sweet's Separators

WHEN "Mike" spits on his hands he does a very natural thing. The tool is slipping because his hands are hard and slippery. Of course he could hold it tighter, but it's easier to soften up the skin. So "Mike" spits on his hands.

We looked at the belt problem this way more than twenty years ago. A leather belt and the palm of the hand are not so very different. Both are skin—one's thicker than the other, that's about all.

The leather is a growth of millions of separate fibres, and is porous. Unlike the hand, it has no life of itself—no natural oils to moisten it—but must be kept mellow and pliable.

A grease should be worked into the belt, where it can surround each fibre and lubricate it from its fellows. Thus they will "run in grease" and slide easily as the belt bends, instead of grating harshly together. The belt becomes pliable and mellow instead of dry and harsh. The surface of the belt will be clean, yielding, "velvety," yet not sticky, and will COHERE with the pulley faces.

Now, any grease so used has got to be a real preservative food, with no harmful acids, and should not oxidize, turn rancid, form sediment, or become stringy. Rosin and rosin oil is condemned by all belting authorities, and various vegetable and mineral oils, in their natural state, cause cracking or rotting within the belt and eventually destroy it.

Sticky belt dressings, while they stop the slipping for a time, are about as bad as glue upon the hands, and for the same reasons.

CLING-SURFACE is a real preservative treatment.

A CLING-SURFACE treated belt will run perfectly in all weathers, easy or slack under big overload, without slipping. It will not warp, tear at the laces, separate at the joints or gather static electricity. With CLING-SURFACE the life of the belt is prolonged, and its capacity for work greatly increased. It immediately becomes a cheerful, obedient worker, soon needing little or no attention, take-up or protection other than the occasional treatment with CLING-SURFACE, and always working easily, silently and efficiently.

CLING-SURFACE can be applied to your belts by any workman in a few hours. A treatment now means a definite step toward permanent freedom from all belt trouble, and money in your pocket, with practically no effort to put it there.

Our co-operation will assist you in this work. Let us send you a can for sixty days' trial.

Remember, use CLING-SURFACE and you won't need belt dressings.

UEHLING WASTE METER

COMBINED

CO_2 AND TEMPERATURE RECORDER

Record of CO2 and stack temperature on one chart.

CO2 Indicator for Boiler Front

Does your fireman know how much fuel he is wasting? Do you know?

The Uehling CO_2 Recorder makes a complete 24 hr. record of your combustion efficiency and the CO2 indicator at the Boiler Front holds the fireman responsible.

Get more Steam per pound of Coal and reduce your annual fuel consumption.

Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

Tycos Temperature Instruments

The Inevitable Choice of the Discerning Buyer

To meet the requirements of those innumerable processes requiring exact *indicating, controlling and recording* of temperature, we have developed the most practical and reliable instruments that can be found.

Recording Thermometers
Indicating Thermometers
Automatic Temperature and Pressure Regulators
Mercury Vacuum and Absolute Pressure Gauges
Engraved Stem Thermometers
Hydrometers
Hygrometers
Thermo-Electric Pyrometers
Radiation Pyrometers

Our more than a half a century of experience as makers of high grade instruments assures you that the *Tycos* Products are as different from ordinary instruments as unusual skill, great care and highest standards of manufacture can make them.

Your inquiries regarding any pecial type are solicited.

Economy fuses effect a saving of 80% in yearly fuse maintenance. Economy Cartridge fuses are renewable. Made in Canada and sanctioned by the Canadian Fire Underwriters' Association. Free Samples of any type supplied with our catalogue No. 24.

Economy Fuse & Mfg. Co. of Canada Limited
Unity Building Montreal

Manufacturers in Canada of "S & C" High Potential Fuses, to 150,000 volts.

Canadian Association OF Stationary Engineers

"The objects and purposes of the Association shall be to promote by all lawful means the efficient operation of steam and electric power plants, and for the said purposes:

(a) To serve as a school of instruction for its members;

(b) To hold meetings for discussing theoretical and practical matters pertaining to its calling;

(c) To examine stationary engineers and firemen as to their proficiency, and to grant graded certificates of ability to its members, and to be a medium through which steam and electric users may be supplied with good and reliable engineers, and to grant relief to its members in cases of sickness and distress."

By joining one of the subordinate associations of the C.A.S.E. you will be greatly benefited. For full particulars write

J. H. Hale, General Secretary, C.A.S.E.

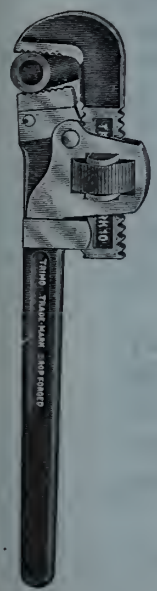
Williams' "Vulcan" Chain Pipe Vises

Only the penny wise begrudge the price of "VULCAN" sufficiency. Experienced buyers will take nothing else.

J. H. WILLIAMS & CO.
THE WRENCH PEOPLE
78 RICHARDS STREET BROOKLYN, N.Y. CITY

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH



Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

Inquiries from Importers and Dealers Solicited. Send for Catalogue No. 55.

LESS COAL

Are you aware that smoke means coal that is lost and wasted? Not only that, but the heat and power units are lost also. So in eliminating this wastage you make a considerable improvement in results and a great saving in cost.

The Jones Underfeed Stoker is scientifically constructed. Every particle of coal is used before leaving the furnace. The greatest amount of heat and power possible is taken from the coal, and this is done without smoke going up the chimney. The actual saving in coal ranges from 25% to 50%. Look your smokestack over and then get out your coal bills.

These stokers have established themselves and gained a reputation. You would make a good move by sending an inquiry.

Jones Underfeed Stoker

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

MACLEAN'S FOR SEPTEMBER

is a magazine of the very best type and rank. It is made for Canadians, and so has a value and appeal to Canadians possessed by no other magazine in the world. MACLEAN'S circulation is getting greater each month. It is now 50% larger than a year ago. The inference is inevitable.

Northcliffe

Lord Northcliffe will be a contributor to the September MACLEAN'S. The general theme of his article will be Canada's position at the present time in relation to the war and to the Empire afterwards. Be sure to read what the brilliant and dominant man has to say about our country. Get an outsider's viewpoint.

MacLean

John Bayne MacLean, publisher, editor, publicist, clear-seeing and far-seeing, has another strong article in the September MACLEAN'S. Colonel MacLean has proved himself to be as clear-sighted as Kitchener in many matters pertaining to the present war; and he is doing a needed work now in THE FINANCIAL POST and other newspapers, to arouse Canadians to a proper sense of the perils that lie ahead.

Ronald

Another smuggling revelation!

A certain Canadian town offered a big bonus to a factory. An American supplied the desired factory, smuggled into Canada the whole plant required,—and was afterwards found out and brought to book. J. D. Ronald tells the whole amazing story in the September MACLEAN'S. Mr. Ronald is contributing to MACLEAN'S a series of Canadian "inside" smuggling stories—true ones. This is great stuff.

Leacock and Laut

Stephen Leacock and Miss Agnes C. Laut are contributors as usual to the September MACLEAN'S. Leacock's humor is bubbling, sparkling and refreshing—like spring water. Miss Laut provides another of her well-informed vigorous, and revealing articles on a phase of the war in relation to Canada and the United States. Miss Laut makes us think and wonder!

Jacobs and McGrath

W. W. Jacobs contributes one of his inimitable short stories to the September MACLEAN'S. "Their Wives Went Along." Harold McGrath, world famous story-writer, who wrote "The Man on the Box," provides a complete novelette. It is a story of adventure and mystery.

Allenson and Moorhouse

A. C. Allenson contributes a short story, "A Flutter in Diamonds;" and Hopkins Moorhouse, "Their Tents like the Arabs." These two men are Canadians—winning fame, and adding lustre to Canada's record for producing short story writers of the first-class.

Hendryx

James B. Hendryx's serial, "The Gun Brand," continues in the September MACLEAN'S. A great story of the Canadian Northwest. The Movie-makers are filming Hendryx's work. So you can be sure that he's writing the right sort of stuff.

Women and Their Work

This is the title of a new department in MACLEAN'S. In the September issue, this department will contain:

Reducing my household cost.

The Care of the Child—an article by Dr. George E. Smith.

A sketch of Mrs. W. M. Davidson, a prominent Western woman, engaged with her husband in editing the Calgary Albertan.

Cooking the Cheaper Cuts,—an article on economy in the kitchen.

This new department will prove of first-class interest to all women.

Review of Reviews

One of the best liked and most valuable features of MACLEAN'S MAGAZINE is its Review of Reviews Department where the best and most significant articles appearing in current literature are condensed for the busy reader, and for the one who wants to know what other magazines are printing. Here one gets a cross-section of the world's best thought.

Inglis Boilers Last a Lifetime

In the Power Plants of Dominion will be found many INGLIS BOILERS that have seen generations come and go. ALL INGLIS BOILERS are made to last, and made to operate at a *minimum expense* and give *maximum service.*

All our Boilers are built to Canadian Standard and are constructed in every way to meet the most exacting requirements.

Sole Canadian Makers of the ERIE CITY TUBE BOILERS. We have a boiler to meet any of your requirements. Let our representative show you some of our installations.

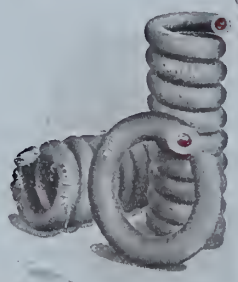
PEERLESS PERFECT PACKINGS

for Every Condition *and* Service



Try it to-day and learn just what Peerless Service means.

KNOWLEDGE of conditions + combination of good materials = a good packing.

There is no one packing that will cover every condition in your plant any more than one coat will fit every man. For this reason the packing that might work on Jones' engine would not give service on yours although they were exactly the same.

Why?

Because the conditions in Jones' plant are different than in your engine-room. You don't care what packing will work in an engine one hundred miles away — you want a packing that will "do the trick" in your plant where you're on the job every day.

That is where Peerless Service comes in — we have over two hundred types and combinations of packings — each one designed to cover certain conditions. All you need do is send fu l particulars and we'll guarantee to give you service with a Peerless Packing.

McEwen High Speed Automatic Engines

For Economical Power Production

These dependable engines are built for continuous duty. They are your best insurance against costly repair bills and unexpected shut-downs.

They operate quietly and smoothly with an exceedingly close regulation under fluctuating loads. Sturdiness and their large reserve capacity enable them to respond instantly to heavy peak load demands.

Your careful investigation of their actual service performance record in all parts of the country is specially requested. Let us send you our list of McEwen users.

Built in simple and compound units up to 700 H.P. capacity. May we send you descriptive literature?

ENGINES, Pumps, Rolling Mills, Pulp Machinery or Planing Mills are given a new lease of life and increased efficiency when Frost King Babbitt Metal is applied. Where great strain is centred on the bearings, this metal proves its value.

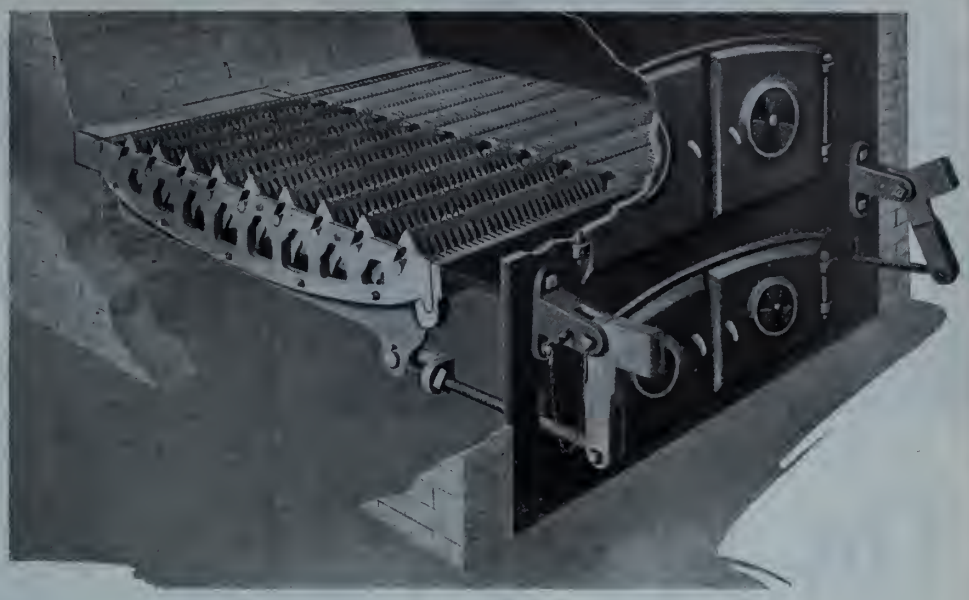
40 years of experience in making Babbitt Metal and a complete study of the uses to which it is applied have enabled us to give you a metal that is as near perfection as modern science can make it.

Our "Nickel Genuine" will do for motors, dynamos, etc., as "Frost King" will do for machinery. An inquiry will bring you immediately complete information. Ask your dealer for it, or write direct to us.

Patented

Anti-Clinker Shell Bar Grates

A Proven Success in Saving Time, Labor and Fuel



Anti-Clinker Shell Bar Grates represent a new and decidedly advanced idea in grate construction.

50 per cent. of the total surface is air space. This abundant air supply commands a perfect combustion which adds *25 per cent.* more heat to the fuel gases and prevents *clinker formation;* the fact of there being no clinkers and an abundant air supply is a guarantee of *greater heat* from *less coal.*

The grate bars as shown in cut are of the triangular pattern, hollow in the centre with *deep teeth.* The under side is open and reinforced every 2½" by cross ribs, so that nothing can remain inside, and makes it impossible to *warp* or *twist.*

Grates taken apart or put together in a few minutes. There's a lot more to tell about the efficiency of these grates. Get in touch with us.

Lessens clinker formation. Always clean. Burns slack, coal, coke or wood. By pressing lever grates are turned to new burn-surface, breaking up coal and giving a clean fire.

Grates cannot twist or warp—two grates in one.

Removes Boiler Scale and Prevents further Formation

SAVE FUEL, OIL AND PACKING

These things we absolutely guarantee you can do by using

BOICO

HERE'S WHAT BOICO WILL DO—Prevent scale from forming; gradually removes all old scale; cut the cost of fuel, oil and packing in a thoroughly practical manner.

HERE'S WHAT BOICO WILL NOT DO—It will not injure packings, valves or any metals; carry over in the steam, foam or prime.

BOICO does not contain any caustics or metallic substances of any kind likely to prove injurious to metal.

Glad to Send You a Package of BOICO on Genuine Free Trial Basis

How would you like to get in touch with users of *Boico?* They include a large number of big plants. Send for their names.

SOME OF OUR OTHER COST-CUTTING LINES

P. P. P.—Daniel's P. P. P. and Ebonite Packings for all Pressures. Only packing backed with scientific proof that it reduces friction. Long tests by Mechanical Engineers proved that P. P. P. saved 75% or more friction losses. Automatically regulates bearings on rod to requirements.

Tip-It Patent Welding Process. Scarcity and high price of high-speed steel compels rigid economy in its use. TIP-IT welding makes it possible to obtain tools with carbon shank permanently united to cutting tip of high-speed steel.

Copper Asbestos Boiler Gaskets—most successful Boiler gasket made. They never blow out and never stick. Made of corrugated copper with pure asbestos, cord filled corrugations. Use them and end all leaks in pipe lines.

DOMINION SUGAR CO., Ltd., KITCHENER, ONT.

The Evidence

This battery of "Jones Stokers" saved over half its cost in a trifle over two months.

This kind of evidence is such that will convince the most critical and skeptical. The savings Jones Stokers have effected in other plants can be accomplished in yours. Think it over.

In many plants a great amount of coal goes up the chimney in smoke. With the "Jones" installed absolutely no smoke is caused. The chimneys are known as "smokeless." The name is well earned. Cheaper grades of coal may be used. The stokers regulate the amount of coal fed in accordance with the demands for steam. Every particle of coal is used, to give its maximum value. You should be one to benefit. We will gladly furnish information.

WHY put in another boiler

WHEN you can increase your present steaming capacity to 200 and in connection with stokers even 300% of the normal rating of the boilers without injury to the boilers by installing a

COPPUS TURBO BLOWER

You will have all the steam you want all the time. Hundreds of satisfied customers will attest to this. No drop in steam pressure when a heavy load comes on, and you can laugh at the weather man, as you can dispense with him for your draft. Besides, the blower will pay for itself in a short time, as it will burn cheaper fuel.

Cut out this Ad., put your name and address on the margin, and mail to us. Without further trouble you will get all the particulars.

500,000 H.P.

In boilers equipped with Coppus Turbo Blowers in four years. The Coppus has replaced a great many other blowers, but no other blower has ever replaced a Coppus.

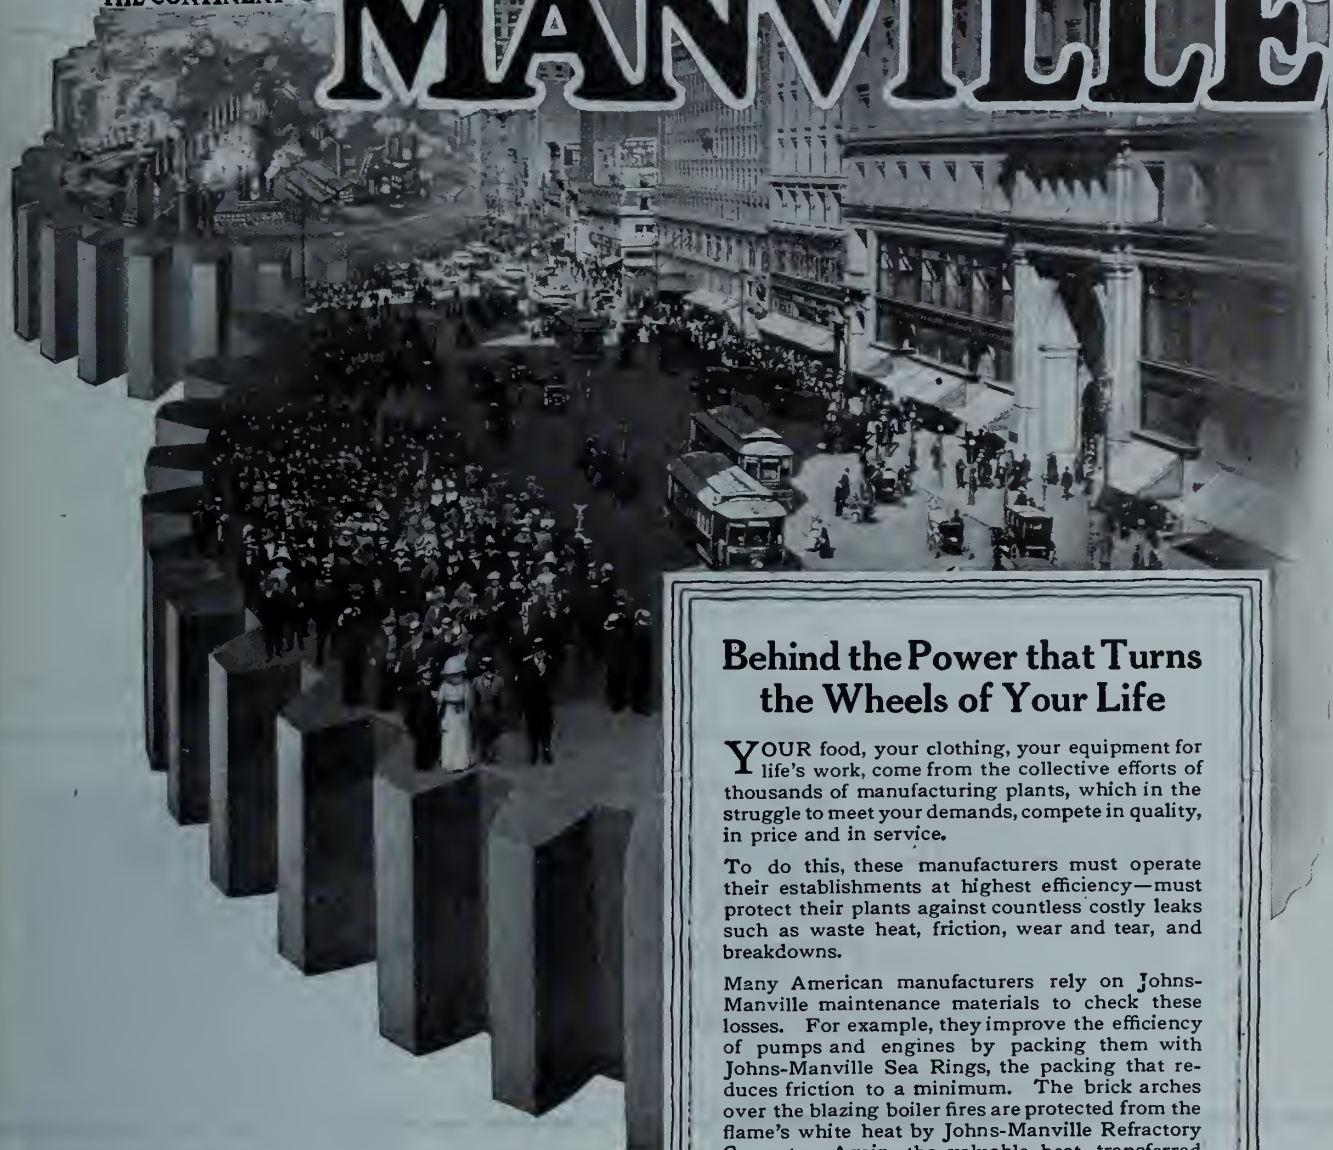
JOHNS-MANVILLE SERVICE
COVERS THE CONTINENT

JOHNS-MANVILLE



Behind the Power that Turns the Wheels of Your Life

YOUR food, your clothing, your equipment for life's work, come from the collective efforts of thousands of manufacturing plants, which in the struggle to meet your demands, compete in quality, in price and in service.

To do this, these manufacturers must operate their establishments at highest efficiency—must protect their plants against countless costly leaks such as waste heat, friction, wear and tear, and breakdowns.

Many American manufacturers rely on Johns-Manville maintenance materials to check these losses. For example, they improve the efficiency of pumps and engines by packing them with Johns-Manville Sea Rings, the packing that reduces friction to a minimum. The brick arches over the blazing boiler fires are protected from the flame's white heat by Johns-Manville Refractory Cements. Again, the valuable heat transferred through pipes, ducts and flues is conserved by Insulations made from Johns-Manville Asbestos and Magnesia. And in hundreds of other instances, Johns-Manville materials are employed to reach you with a better product at the lowest cost.

So that of all the ways—some direct, some devious—by which Johns-Manville serves the public, none is more important than this function of maintenance, this power economy at the very heart-center of industry.

How Much Refrigeration Are You Losing?

Do you know how much you can save by having your cold pipes covered properly? The season for making repairs and putting your plant in first-class shape is at hand. Wouldn't it be a good plan to get as much information as possible and look into the merits of

Nonpareil Cork Covering
For All Cold Pipes

before it is too late?

This 64-page book covers the subject of cold pipe insulation pretty thoroughly. It does not make broad, general statements, but gives you real information that will enable you to figure out for yourself just how much refrigeration you are losing through your bare, cold pipes. In fact, it is not a book that you will glance through and then throw away, but one that you will keep for reference purposes.

The book is free. Just mail the coupon to-day.

ARMSTRONG CORK & INSULATION CO.

Something New

In the 4th Edition of our Fittings Catalog, recently issued, we illustrate a line of SCREW AND FLANGED AMMONIA FITTINGS, supplementing the large line of Standard YORK Valves and Fittings which are coming into more general use each year.

This is in line with our policy to design and place on the market Fittings and Apparatus that will make the application of MECHANICAL REFRIGERATION more convenient and economical.

From the number of orders received, it is quite evident that these SCREW AND FLANGED FITTINGS have met with the endorsement of the practical Engineer.

By their use YOU can—

SAVE WEIGHT WITHOUT LOSS OF STRENGTH OR CONVENIENCE.

ELIMINATE *ONE-HALF* THE *GASKET* JOINTS.

DO MORE RAPID PIPE FITTING, by ELIMINATING *ONE-FOURTH* OF *ALL JOINTS.*

as compared with full flanged fittings.

There is but ONE Effective Method of preventing or correcting Feed Water Troubles—
Scale, Corrosion, Pitting, Bagging and Foaming
it is
Dearborn Treatment

WE are and have been for 25 years primarily interested in the scientific investigation of water, as related to steam boiler economy; determining, by careful analysis of boiler feed supplies, what properties there are in such waters that eat their way into boiler plates, form scale, produce leaks, corrode the iron, and cause many other evils well known to steam users; and preparing reagents, combined scientifically to meet individual water conditions that will successfully combat these elements.

Our laboratories make complete mineral analyses free of charge for plants interested in obtaining relief from their boiler water troubles.

After the analysis is completed we furnish reports of our results, and advise definitely regarding treatment required, cost per thousand gallons of water, method of applying treatment, etc.

Let us advise what we can do for you. Send a gallon sample of your feed water to-day.

Pass It Along

A SHORT time ago the writer called on an engineer in charge of a very large plant and was shown through the engine and boiler rooms.

In the course of our conversation the engineer described how he had overcome certain problems. The troubles he had encountered were typical of the problems other men are running up against constantly and his method of overcoming them would interest scores of brother engineers.

"Why did you not write POWER HOUSE telling our readers about this?" I asked my friend the engineer.

"Well to tell the truth," he replied, "I have thought of it but have never got round to it. I never seem to have time."

Now, friends, this engineer had an assistant and admitted that he had a certain amount of spare time—enough indeed to spare for writing POWER HOUSE describing the "kinks" referred to. The trouble was he hadn't tried as hard to overcome the problem of finding time to write as he had tried to solve his engineering troubles!

An idea printed in POWER HOUSE multiplies in usefulness many hundred fold. It doesn't take long to pencil a few lines and make a rough sketch and yet this is all our editor requires to properly present your idea.

Scores of engineers may be able to make use of that pet scheme of yours. Why not simply **make** time and send us particulars? It would really be a generous act on your part and if it came right down to the fine thing it might be considered just a little selfish if you didn't do that much to help your brother engineer. (We will gladly pay you for any contribution you may send us).

And don't think it entirely necessary to contribute an idea when you write us. If you have a problem and find yourself stumped tell our engineer-readers. Some fellow may be able to help you right off the bat, having discovered the solution to your problem through experience dearly bought at some time or other. It may never occur to him, however, that someone else might be stuck just as he was.

POWER HOUSE is yours for service and for greater service. It is out to help you and no expense will be considered too great and no trouble will be spared to help you. But the greatest help to the greatest number will be given when **YOU** feel moved to throw off that little bit of indifference and pass along your ideas. It will do you no good to keep them hidden in your own plant. It **will** benefit hundreds of others if you pass the good word along. And that's what makes life worth living. It's what enables some people to live such full and such happy and useful lives.

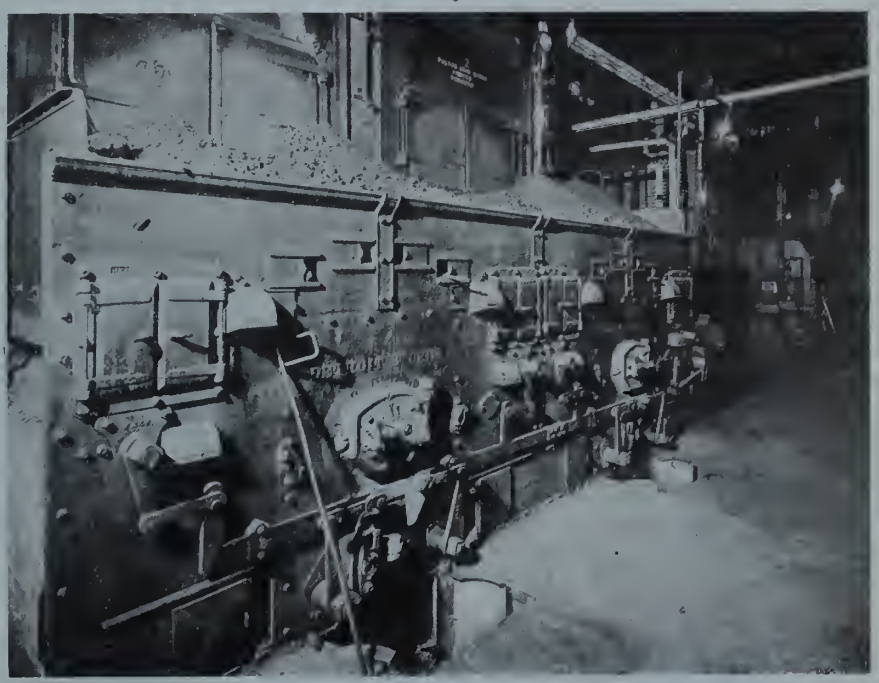
Power Equipment Installation for Candy Manufacture

Staff Article

To secure a big scale output of candy and chocolate products demands as a manufacturing auxiliary a modernly equipped steam-electrical power plant. To those of us located in the cities of this Dominion, it is readily apparent that the consumption of candies — wise or otherwise, has assumed enormous proportions. To meet the situation, an industry of considerable scope has been developed, and in the matter of individual plants, that treated in the accompanying article may be taken as a typical example of the many existent.

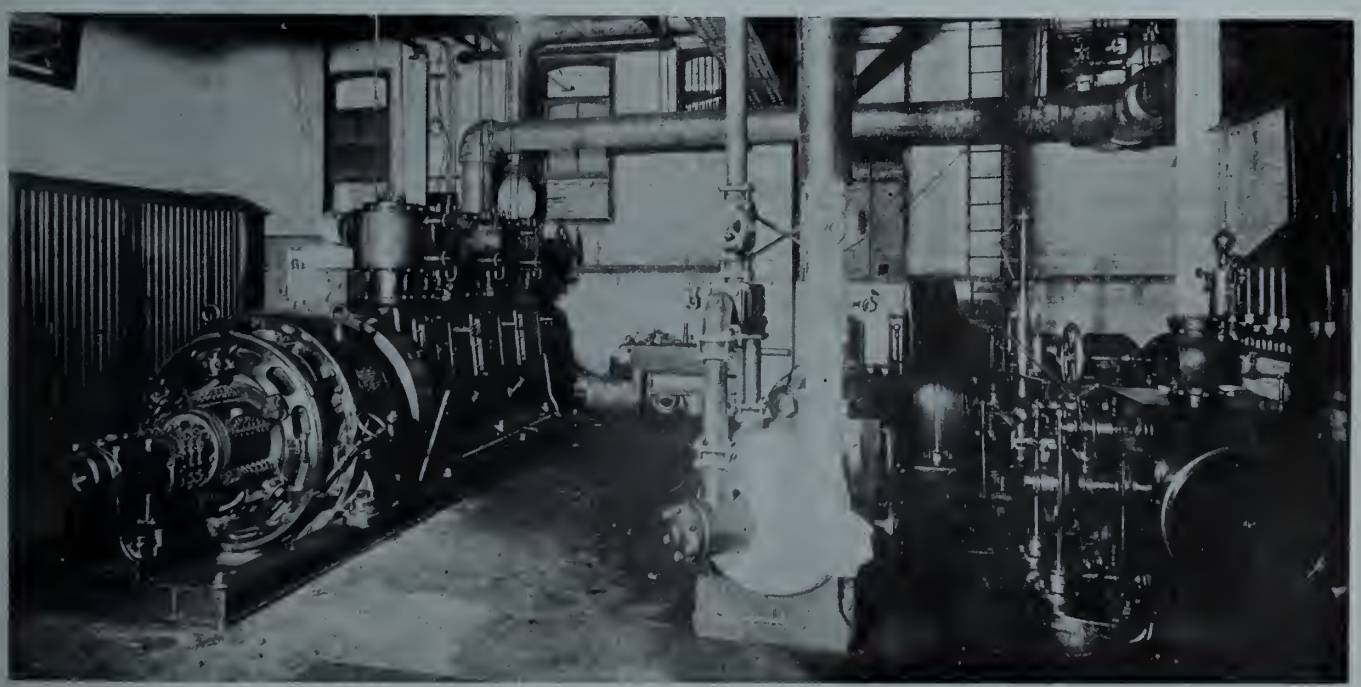
THE old established firm of Robertson Bros., Ltd., Queen Street East, Toronto, is one of the leading concerns in Canada manufacturing candy and chocolate products. The business has in recent years increased considerably in volume and consequently more power was required for operating the factory. Although the power plant is not entirely of recent date, new equipment installed during the past year has brought it more or less up-to-date besides increasing the power available by 450 h.p. and providing a fair reserve for future requirements. The new power units consist of 300 h.p. and a 150 h.p. Ashworth-Parker high speed engines, also two 125 h.p. return tubular boilers. At the time the capacity of the power plant was increased the boiler room was rearranged, the three existing boilers being replaced by new ones and Detroit stokers installed throughout.



BOILER ROOM SHOWING "DETROIT" STOKER INSTALLATION.

Boiler Room

The boiler installation consists of five return tubular boilers arranged in two batteries of three and two respectively, all having been installed recently. The three boiler battery units are each 66 in., diameter by 14 feet long and are rated at 100 h.p. while the two boiler battery units are each 72 in., diameter by 16 feet long and are rated at 125 h.p. each. The 100 horse power boilers were built by the International Engineering Works, Amherst, N.S., and those of 125 horse power by the Polson Iron Works, Toronto. The working pressure is 115 lbs. per sqare inch, which is reduced to 90 lbs., for the boiling pans, etc., in the factory. The boilers are all equipped with Dutch oven furnaces and Detroit mechanical stokers, the latter being arranged in two distinct units as



SHOWING "ASHWORTH-PARKER" 250 K.W. ENGINE WITH L. D. & M. CO. GENERATOR, AND 65-TON "YORK" STEAM-DRIVEN AMMONIA COMPRESSOR.

the two batteries of boilers are separated from one another.

Pumps

The pumping installation is located midway in the boiler room between the two batteries of boilers and comprises the vacuum and boiler feed pumps. There are three boiler feed pumps which include the following:—One Worthington, duplex, horizontal, pot valve pump, 9—5—10 ins.; one Northey 6—3½—7 in. horizontal, outside packed, plunger pump, and a tandem duplex pump by the Canadian Steam Pump & Machine Co. The returns from the low pressure heating system are taken care of by two 8—14—12 ins. vacuum pumps supplied by Deane Bros., Holyoke, Mass.; there is also a Martin vacuum pump as a reserve unit. The heating system is supplied with exhaust steam from the engines, the returns being pumped to a 700 h.p. Otis feed water heater located in the boiler room. The condensation from the boiling kettles and other steam equipment in the factory is returned to the boilers under pressure by means of No. 3 Morehead and No. 7 Cole return traps, located on top of the boilers.

SHOWING 150 K.W. "ROBB" HORIZONTAL ENGINE WITH C.G.E. GENERATOR, AND "ASHWORTH-PARKER" 100 K.W. VERTICAL UNIT WITH L. D. & M. CO. GENERATOR.

Engine Room

The company generates all its own power for the factory motors and lighting system, which is direct current throughout. There are three steam-driven generating sets giving a total of 675 h.p. exclusive of the steam driven ammonia compressor. The three steam engine units consist of the two Ashworth-Parker high speed engines installed recently and a Robb-Armstrong high speed engine installed at an earlier date. The Robb engine is an enclosed horizontal 150 k.w. unit, 17 x 16 inch cylinder, direct connected to a Canadian General Electric direct current generator of 120—240 volts, 600 amperes, and running at 225 r.p.m. The other two units were built by Ashworth & Parker, Bury, England, and were supplied through the G. H. Tod Co., Toronto. The larger engine is a non-compound, vertical, enclosed high speed unit of 250 k.w. and has three high pressure cylinders each 16 in. diameter by 8 in. stroke. Its rating is 300 h.p. when running at 450 r.p.m. This engine is direct connected on the same sub-base to a 225 volt, 900 ampere, direct current generator built by the Lancashire Dynamo & Motor Co.

The smaller unit is 100 k.w., of the same type, but having two cylinders each 14 ins. diameter by 7 ins. stroke. It is direct connected to a 100 k.w. 3 wire, compound wound, 250 volt, 400 ampere, direct current generator running at 500 r.p.m. This generator was also built by the Lancashire Dynamo & Motor Co. Both engines are equipped with Charlton Whitehead governors ensuring a maximum variation of 2 per cent., no load to full load. Each generator is compound wound and fitted with interpoles to give sparkless commutation at all loads, also 3 wire equipment consisting of slip rings and static transformers capable of dealing with an out-of-balance current of 20 per cent. The full load efficiency of the 250 k.w. generator is 92 per cent. and of the 100 k.w. generator 91 per cent.

Switchboard

The switchboard has five panels of grey marble and is 6 ft. by 11 ft. It was supplied and equipped by the Canadian General Electric Co., Toronto. The first panel controls the Robb engine generator and has a circuit breaker, 600 ampere double throw switches, and two ammeters. The second panel is for the 100 k.w. steam driven unit and has a circuit breaker, 400 ampere switches and also two ammeters. The third panel controls the 225 k.w. generator, and has a circuit breaker, 900 ampere switches and two ammeters. The fourth and fifth are distributing panels and have a number of switches controlling the different sections of the factory. At the left hand side of the board are two volt meters on a swinging bracket. There are approximately 40 motors in the factory ranging from ¼ to 40 h.p. The lighting system is 3 wire, 120 volts, d.c.

There are several chocolate cooling rooms in the factory and in connection with these is a refrigerating unit installed in the engine room. This unit is a 65 ton York horizontal, steam driven, ammonia compressor operating on the direct expansion system. The steam engine, which is of Corliss type, has a cylinder 20 in. in diameter by 20 in. stroke and the ammonia compressor has a 14 inch cylinder by 24 in. stroke.

GASKET MEMORANDA

A THIN gasket is best where joint surfaces are smooth, and is less likely to blow out than a thick one.

Gasket seats should be well cleaned and pieces of old gasket removed before placing the new gasket in position.

When installing a gasket, the object should be to apply, when setting up on it, an even, well-distributed pressure over as large a part of the surface of the gasket as possible. Nuts should not be set up too tightly in the beginning, but should be followed up as found necessary to prevent leaks when the steam pressure rises.

Cases have been experienced where handhole plates were set up so tightly with a long-handled wrench that the new gasket was mostly squeezed out of the joint and its structure torn in places. These small crevices or torn places form small openings, through which steam soon leaks, and the only remedy is to replace the gasket which has been ruined.

Gaskets with too wide a flange surface, or carelessly put in place, may project too far beyond the edge of the joint and jam the handhole or manhole cover at that point, so it cannot be set up or made to seat propertly.

Gaskets of compressed fiber sheet are likely to tear when the joint is broken and to leave pieces of the old gasket sticking to the metal. These often form high spots which are easily overlooked, and likely to cause leaks and the condemnation of new gaskets which are not faulty.

ROPE CAPACITY OF A DRUM

A CONVENIENT rule for computing the rope capacity of any sized drum is as follows:—Add the depth of flange in inches to the diameter of the drum, and multiply this result by the width (out to out) of the drum. This product is then multiplied by the figure below corresponding to the size of rope used:—

¼	in.	4.16	1⅜	in.	.138
⅜	in.	1.86	1½	in.	.116
7-16	in.	1.37	1⅝	in.	.099
½	in.	1.05	1¾	in.	.085
9-16	in.	.828	1⅞	in.	.074
⅝	in.	.672	2	in.	.066
¾	in.	.465	2⅛	in.	.058
⅞	in.	.342	2¼	in.	.052
1	in.	.262	2⅜	in.	.046
1⅛	in.	.207	2½	in.	.042
1¼	in.	.167			

Engineering Exhibits at the Canadian National Exhibition

Staff Article

The value of Canada's premier Annual Fair as an occasion on which to gain publicity is again justified by a visit to the Machinery Hall, while any doubts regarding the mechanification of the farmer are instantly dispelled by an examination of tractors, electric light plants, and other aids toward a labor-saving and luxurious existence for sons of the soil.

DESPITE the absence of a few notable exhibitors of former years, the engineering features of the exhibition, both in the Machinery Hall and elsewhere, have aroused probably a more wide-spread interest than for many years past. The fact that many people, brought in contact with engineering practice through the temporary activity of munitions production, are now earnestly endeavoring to find a permanent outlet for their efforts is one, if not the main reason for the great general interest displayed by visitors this year.

PART OF PRATT & WHITNEY'S EXHIBIT OF SMALL TOOLS.

Present conditions, of course, have postponed any improvement in the facilities afforded exhibitors, but had proper and deserved encouragement been given in a timely manner, the machinery display would not be handicapped by comparison with certain annual events in the States, which are noted for the facilities offered exhibitors in such important matters as steam, gas, air and electricity supply, especially in the matter of reasonable charges for the latter service. As matters are now, it is only through the loyalty and patriotism of exhibitors, who annually face the expense and inconvenience of two weeks' dislocation of regular business, that the standard of the show has been maintained at its present level. In view of the services rendered to the Empire, and the great degree of confidence with which the industry is regarded as a mainstay of the country in the future, no excuse short of absolute lack of funds can justify a continuance of the present lukewarm attitude of the authorities toward engineering exhibitors. The thanks of the industry are indeed due to those who continue to "carry on."

The general state of affairs is indicated by one noticeable change in the aspect of the show—munitions have disappeared and manufactures are returning. Machine tools are the heavyweights, as always, but developments largely due to the recent munitions activity are indicated by several of the exhibits. One of these is the increasing appreciation of the benefits of heat treatment in certain classes of work, and in this field much initiative has been displayed by the Canadian Hoskins Co., the well known pioneers in electrical furnace and pyrometer development. Their product now includes also gas-fired furnaces, ovens for enamelling, etc., and a unique product in the shape of Chromel, a non-ferrous alloy, which possesses marked non-corrosive properties, especially under the influence of heat. These properties are due to the high melting point of chromium combined with the great resistance of nickel to oxidization. This metal does not soften appreciably under heat like iron and has a life approximately 40 times as long. Applications already proven include carbonizing boxes, cyanide crucibles, lead pots, barium pots, pyrometer protecting tubes, etc.

It is of especial interest at this time to know that this alloy is made in Canada in the Hoskins factory, an important part of the process being played by a special type of carbon resistance furnace which is also exhibited. Its simplicity of construction and efficiency of operation render it particularly useful in high temperature work.

Further interest in the combustion field is stimulated by the extensive display of manufacturers furnaces exhibited by the Consumers' Gas Co. of Toronto. Apparatus and equipment for the convenient use of gas as a heat-producing agent in many lines of industry are shown in operation, gas and air being piped to most of the exhibits. High temperature furnaces for special steel hardening, tool room furnaces, ovens, brazing benches and blow pipes demonstrate clearly the adaptability of gas to many processes. The effect of several furnaces at white heat is very marked from a display viewpoint, the entire exhibited being markedly effective.

Of similar interest to visitors is the demonstrations of oxy-acetylene welding work. L'Air Liquide Society show the use of their apparatus in the manufacture of storage tanks for acetylene gas, to withstand 975 lbs. pressure per sq. in. A sample of liquid air, which is produced during the manufacture of oxygen was an item of more than ordinary interest, in which one could test the effects of 350 deg. below zero on the human flesh. Mechanical apparatus for the application of the oxy-acetylene flame to manufacturing operations were featured by the Carter Welding Co., who showed the well known Davis-Bournonville apparatus cutting steel plates of any thickness and shape. The radiograph is an ingeniously arranged machine on the pantograph principle, which enables patterns to be copied

THE CONSUMERS' GAS CO. EXHIBIT ED GAS FURNACES IN OPERATION.

on large or small scales, the flame cutting the outline as determined by the master design; the roughing out of dies and similar work is a particularly useful field for this device.

Special appeal is made to the skilled mechanic and fine tool maker by the Pratt & Whitney exhibit of Canadian-made cutters, reamers, taps, drills, shell tools and special articles of a similar nature. The prestige attached to the name is well upheld by this exhibit, which is convincing evidence of the possibility of producing such goods on a commercial scale within the Dominion. Complementary to the foregoing are the machine tool exhibits of Canada Machinery Corporation, Garlock-Walker Machinery Co. and A. R. Williams Co. Both wood and metal-working machines are displayed on a large scale by the former, whose annual appearance is looked forward to with interest by a wide circle of acquaintances. A feature of Garlock-Walker is the showing of numerous views in lantern slide form, illustrating iron machinery from the raw state to the finished product. The entire history of iron is shown from the blasting of the rock by the miners, through railroad yards, ore docks, blast furnaces, steel mills and foundries, pattern shops and machine shops till it assumes the form of a lathe, shaper or other machine tool, and demonstrates most convincingly the absolute dependability of modern manufacturing on this one metal more than any other. Suitable types of modern tools are on view to complete the exhibit.

THE CARTER WELDING CO. SHOWED MECHANICAL APPARATUS FOR CUTTING AND SHAPING PLATES WITH OXY-ACETYLENE FLAME.

CLEVELAND PNEUMATIC TOOLS INCLUDED SPECIAL DESIGNS FOR WOOD SHIPBUILDING.

A feature of the Williams exhibit is the demonstration of Stellite cutting tools on heavy forging machining. This wonderful alloy depends for its existence entirely on the Canadian deposits of cobalt, and during recent times has earned a wonderful reputation as a metal-cutting material. Numerous samples showing its application to tools for a wide range of operations are displayed by the Deloro Smelting & Refining Co.

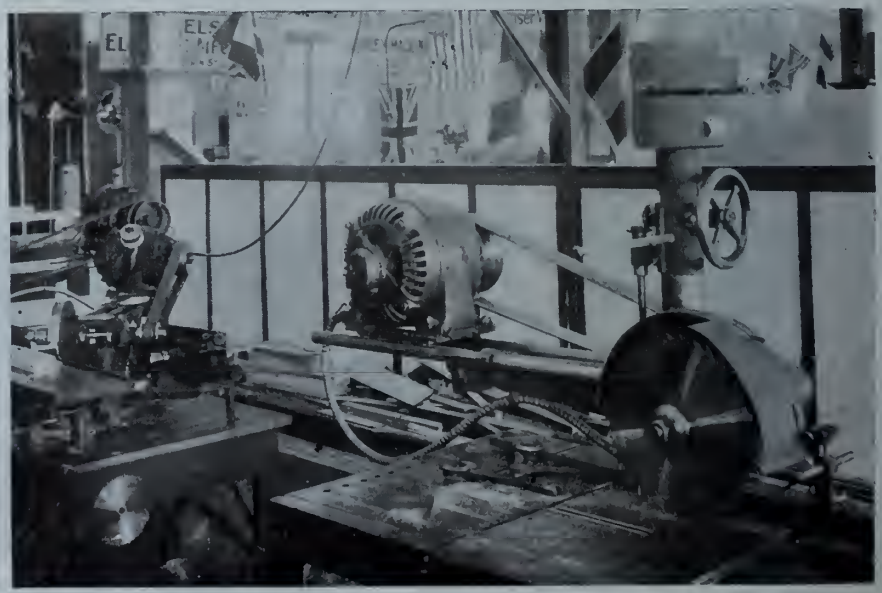
Pneumatic tools and accessories possess considerable interest in view of their labor-saving and cost-reducing ability. The development of shipbuilding both in wood and steel has been carefully studied by the Cleveland Pneumatic Tool Co., and special wood-boring machines and drifting hammers are featured by them in addition to their latest types of regular hammers and accessories.

Transmission equipment and apparatus is featured by the Dodge line, one of the items of interest being an exhibit showing their wood pulley in different stages of construction, from the plain board of selected lumber to the perfectly finished wood-split pulley seen on the shafting. Ball bearing developments are also well shown, the increasing recognition of this apparatus as an efficiency factor being evidenced by the presence of the Canadian SKF Co., Ltd., which makes a convincing demonstration of the extreme accuracy and high grade of workmanship in their product. The exclusive feature of self-alignment which is an inherent part of the design is shown by means of bent shafts, which revolve as freely in a fan draft as if they were straight and true. The Chapman Co. makes an effective display.

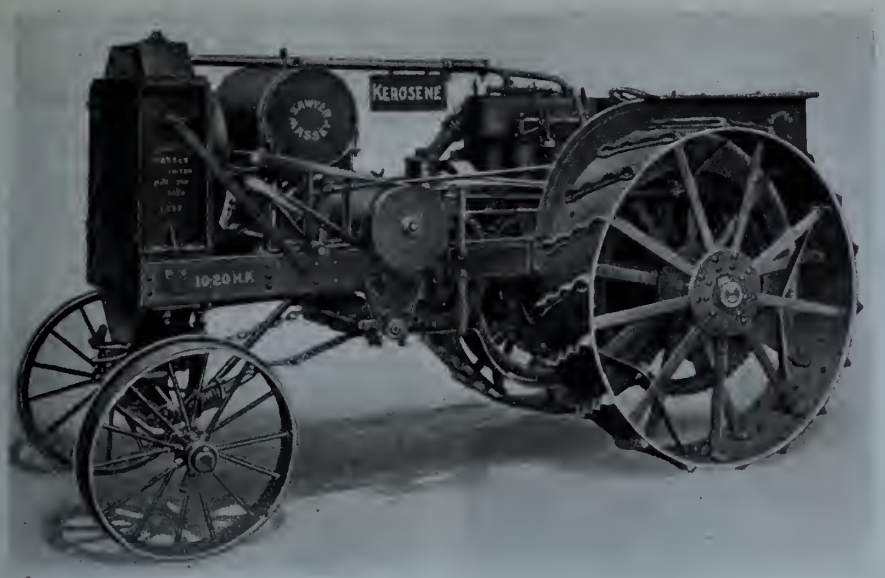
Belting exhibits are quite noticeable especially as most of the displays represent made in Canada goods. Of the four firms showing, each makes a distinctive type of product. Leather, rubber, and two varieties of stitched belting are available in weights, strengths, and finish for any kind of industrial need. Considerable local interest attaches to the two displays of that modern development of the saw bench known as the combination woodworker, one firm in particular having developed considerable business across the line.

The Goodyear Tire & Rubber Co. made an interesting display of a wide range of products, from heavy duty belting of large size to packing, jointing and similar engine room supplies.

Special interest attached to the exhibit of D. K. McLaren, Ltd., whose display of leather belting maintained their high standard of former years. Despite the present state of the leather market, they continue to feature the use of all British oak tanned stock in the belts which they manufacture, the superior strength, flexibility and long life of belting produced by this process being well



THE HUTCHINSON WOOD-WORKER PERFORMS LARGE VARIETY OF OPERATIONS.



SAWYER-MASSEY 12-22, 4 CYLINDER, KEROSENE DRIVEN TRACTOR.

known. Both balata and canvas belting were exhibited, suitable for power transmission and conveyor duty, while woolen and knitting mill supplies possessed features of interest to many power users. Both wood and steel split pulleys were also shown, together with a large variety of belt fasteners and lacing machines.

The Dominion Belting Co. showed their line of Canadian-made stitched cotton duck belting, in all sizes and weights for both conveyor duty and power transmission, along with belting accessories. The Main Belting Co. of Canada had also a very complete display of their product, which finds application in many fields of industrial activity.

Steam traps, boiler return systems, heaters, etc., were exhibited both in full size and models by the Geo. W. Cole Co., who showed a complete installation of a double trap taking care of returns from low pressure and high pressure systems simultaneously. A No. 7 trap to handle 600 horse-power was also shown, as well as condenser and three-valve types. The Cole system of packing was shown by means of a model trap.

Agricultural Engineering

Either engineers or farmers desirous of investigating farm apparatus which is the direct product of the machine shop find more than ample opportunity in the section devoted to this display. The present question of food control has thrown the production end further into the spotlight than might have happened in years, and the fierce blaze of criticism is turned loose on the numerous specimens of tractors, oil engines, pumps, electric lighting plants, along with other quasi-machine shop products such as milking machines, and similar products.

As a Canadian built product, the Sawyer-Massey line of tractors makes a special appeal. Simplicity of construction has been combined with convenience and efficiency of operation in a markedly successful degree. The 4 cyl. vertical automobile type of motor is placed near the rear axle to give maximum adhesion, and allows the transmission case and jack-shaft to be placed amidship in a most accessible position. The clutch likewise benefits thereby, while the train of reducing gears to the driving wheels is also made very accessible. Approved

EXHIBIT OF CANADIAN S K F CO., SHOWING DISTINCTIVE FEATURES OF THEIR SELF-ALIGNING BEARINGS AT CANADIAN NATIONAL EXHIBITION.

EXHIBIT OF GEO. W. COLE, LTD., STEAM SPECIALTY MANUFACTURERS, WHO SHOWED APPARATUS IN OPERATION.

design of steering gear with spring buffers is fitted to front wheels. Water cooling with fan radiator is incorporated in the design in a suitable manner the radiator construction being exceptionally robust. The motor is 4 in. bore by 6 in. stroke running 700 to 1,000 rev. per min., and gives 22 horse power at the belt pulley and 12 at the draw bar. Two speeds of 2¼ and 3½ miles per hour are provided, while weight of 5,200 lbs. enables three to four plows to be operated.

Allis-Chalmers exhibited a 10-18 horse-power machine of the three-wheeled type, the single front wheel following the furrow automatically and relieving the operator of much of the steering effort. It is operated by a 2-cyl. opposed type motor, 5¼ by 7 inch at 720 rev. per min. and weighs 4,800 lbs. The frame is a one-piece steel casting, heat treated, while the radiator is of the automobile type with centrifugal pump.

OAK TANNED LEATHER BELTING WAS A PROMINENT FEATURE IN THE DISPLAY OF D. K. McLAREN, LTD.

The 9-18 Case tractor was shown by the Fairbanks-Morse Co., and attracted attention through its compact and wonderful hill climbing ability demonstrated on a 35 deg. incline. As illustrated the motor which is 8 cyl. vertical, is placed athwartships so as to obtain straight spur drive to rear axle. The front axle is pivoted vertically at the centre, with steering knuckles on the wheels. A truck type of radiator is fitted in conventional manner and has gear driven fan, and centrifugal pump circulation. Heavy duty roller bearings are used wherever desirable, including the transmission, and rear axle, and an oil tight housing encloses the bull pinion and gear. Two speeds are obtainable, along with ample power to pull two 14 in. plows.

CASE 9-18 AUTOMOBILE TYPE TRACTOR WITH 4-CYLINDER MOTOR PLACED TRANSVERSELY.

Good advice for power plant men—when in doubt, don't do it; be sure you're right, then go ahead.

ALLIS-CHALMERS THREE-WHEELED TRACTOR IN OPERATION ON A FARM.

PREPARING HEATING BOILERS FOR SERVICE

AS the winter season approaches, householders and other owners of heating boilers begin to make plans for placing the boilers in service. Persons who earnestly desire to obtain the best results from their heating plants, and who give careful thought to securing economy in operation and obtaining maximum length of service from their equipment, — in other words, all thrifty and methodical managers,—will have had their boilers well cared for at the time their operation was discontinued in the spring, so that in restoring them to service there will be little to do except to close up the various openings, supply the necessary water and start the fires.

The precautions that should be observed in laying up boilers, in the spring, were outlined in the Travellers Standard some three years ago. Commenting on the preparation of boilers for service, it says: If these have been faithfully observed the boilers should be in good condition in the fall, both internally and externally; but if they have been neglected, the delay has doubtless affected the heating equipment detrimentally, so that any defects that existed in it have probably grown worse, and deteriorating influences of various kinds have doubtless produced notable results during the period of idleness. In such cases, therefore, it is important to look the heating plant over with special care, to remedy the effects of neglect as far as possible. Some of the advice that is given below is based upon the assumption that the boiler was not properly cared for in the spring, and other parts of it should be heeded, whatever was done at that time. The reader will have no difficulty in distinguishing the parts that apply to his own case.

Internal and External Cleaning

Before filling the boiler with water, clean every accessible part of it thoroughly, both internally and externally. Take down the smoke-pipe and remove the soot from it, and in the case of tubular or flue boilers thoroughly clean out the tubes or flues. When the smoke-pipe has been replaced, examine the joints carefully and make sure that they are tight, and give attention also to the supports for the pipe.

An equal amount of care should be exercised in cleaning the external surfaces of the boiler itself. All soot, dust and ashes should be removed from the setting, boiler and grates. See, also, that the brickwork of the setting is in good repair.

Do not forget that the gage-cocks and the connections to the water column may have become filled up. Make sure that they are free, even if it is necessary to remove them from the boiler for the

purpose; and in the subsequent operation of the boiler do not rely upon the water glass to implicitly for determining the height of the water, but confirm its indications by the frequent use of the gage-cocks.

Attention to Corroded Parts

If the water was drawn off in the spring without drying out the boiler afterwards, or if the feed valve has leaked during the summer, small quantities of water may have remained upon the boiler surfaces for a considerable time. In this case corrosion and pitting have doubtless occurred to some extent. All areas affected in this way should receive special attention. If possible, the water should be removed, with a mop or otherwise, and the metal allowed to dry. The plates should then be scraped, or thoroughly cleaned with a stiff wire brush, and it is often well to paint the affected places with red lead and oil, or with some special protective preparation, after the dirt and oxide have been entirely removed. When this has been done, and sufficient time has been allowed for the paint or other protective substances to dry, the boiler should be filled with water and drained off again at least twice; and if the construction will permit, a hose should be used to wash out any sediment that may remain. In filling the boiler leave a vent open somewhere, for the escape of the air it contains. Opening the upper gage-cock suffices for this purpose, if the boiler is to be filled only to the working level; but if it is to be completely filled, the safety-valve should be eased from its seat, or some other opening should be left at or very near the top of the boiler to prevent the trapping of air in the upper part of the boiler.

Whenever it is feasible to do so, the safety-valve should be tested by hydrostatic pressure before the boiler is placed in service, to see that it operates at the pressure for which it is supposed to be set.

Look over the boiler accessories and attachments with special care. Raise the safety-valve from its seat, and if it does not work freely, or if any part of it is in need of repair, see that the trouble is made right before firing up the boiler. The diaphragm of the automatic damper regulator also requires a critical examination. See that it is soft and pliable, and if it is found otherwise, have it removed and replaced by a new one. See. also, that the diaphragm, with its connections and the dampers that it regulates, works smoothly, easily and positively.

Starting Up

The fire should be run very low at the start, to permit the boiler and its contents, and the various other parts of the system, to become heated up gradually. The supply and return valves of the heating system should be opened so that the steam, as soon as it is generated (or the hot water if the system is of the hot-water type), will warm up the pipes gradually. Pounding in the pipes will be averted in this way, and the danger of rupturing the cast-iron fittings by rapid and unequal expansion of the piping will also be diminished. As soon as steam has been raised, the safety-valve should again be lifted, to see that it is free and in good working order. It is also well to run the pressure up to the point at which the safety-valve is supposed to blow, in order to make sure that it will operate properly under regular running conditions.

Skilled Examination Necessary

The boiler owner or attendant who has faithfully complied with the foregoing suggestions may feel reasonably confident that his boiler is in condition for safe and efficient service, unless the deterioration that it has experienced during the summer season has been very marked. It will probably give no trouble if it is in charge of an experienced and trustworthy attendant, who will see that it is properly supplied with water, and that the safety-valve, damper regulator and other accessories are kept in good working order. It is important, however, to have the boiler examined by a competent inspector, who will look over the entire equipment thoroughly, to make sure, so far as possible, that everything is in good condition, and to test and regulate the safety-valve and the steam-gage. Many boiler insurance companies render service of this kind to their policyholders, free of charge; and also give valuable expert advice on all matters relating to boiler management. The counsel that is given in this article will prove helpful in promoting safety and economy, but no article could be written that would make it wise to dispense with the services of an experienced inspector. One might as well dispense with his family physician, after reading a little of the elements of physiology and materia medica.

The Second-Hand Boiler

A considerable number of second-handed heating boilers will doubtless be installed at about this time, and many that are in poor condition, or even positively dangerous, may be accepted by inexperienced persons, upon the representations of unscrupulous or misinformed salesmen. A coat of paint often makes a poor boiler look good to a novice. Here, also, the services of insurance inspectors are valuable, because their training enables them to detect weaknesses and defects that would easily escape the attention of persons with less experience.

GRAPHITE REMEDY FOR BOILER SCALE

A VERY finely powdered graphite placed in a boiler immediately after it has been cleaned, circulates with the water, and rubs against the steel, to which it imparts a graphite finish or polish on which scale does not readily form. When this initial dose is regularly followed up by smaller doses, the graphite, by mechanical, not chemical, action gradually softens and disintegrates any old scale that may still be present, and if new scale thereafter forms, and it almost always will to some extent, it forms in and with that scale, so that all may be easily broken up and removed. Inferior grades cannot with safety be allowed into steam boilers.

The graphite in cheap grades is impure, containing, perhaps, only 20 to 50 per cent. graphite carbon. The impurities consist of clay, silicate, etc. which means that for every 100-lb. used there would go into the boiler from 50 lbs. to 80 lb. of scale-forming substance, which, with the impurities in the feed-water, would be too much for the 20 lb. to 50 lb. of graphite carbon to influence. The cheap grades are, also, coarsely ground. Graphite, to do the work properly in a boiler, should be so impalpably fine that it will remain suspended in the water and circulate with it. Amphorous graphite gives the best results, both for lubricating and for removing and preventing scale. Flake graphite will not do the work as well. The graphite mined in Mexico is said to be the best for steam boilers.

OBSERVATIONS ON ROPE DRIVE PRACTICE

IT occurs to us that conditions and circumstances enter more largely into the determination of the various details constituting a rope drive than have to be accounted in that of a belt drive, therefore the following notes and observations on rope drive practice may be found interesting and useful:

Manila and cotton are the materials generally used for rope purposes, and may be constructed of 3 or 4 strands. The rope diameters in practice vary from 1 to 1¾ inches, although those below 1½ inches are somewhat uncommon. From investigation it has been computed that the safe and economical dorking strain for a 1 inch diameter rope is 200 pounds, with equivalent for other sizes. Rope wear is both internal and external, caused in the former by the movement of the fibres on each other, and in the latter by slippage and wedging in the pulley grooves. This wear, of course, is normal, and is dependent on the speed of drive.

As in belt drives the advantage lies with large diameter pulleys, the tendency being to less internal wear, due to fibre sliding decrease, with diameter increase. Care should be taken to have the grooves ground out smooth and of unbroken surface, so as to obviate unnecessary wear or tearing of the external surface of the rope. The groove angle may be 45 to 60 degrees. Rope wear is independent of pulley distance apart, because it takes place on the pulleys only; at the same time distance is a factor in first cost.

Experience goes to show that 80 feet per second is the speed at which the maximum horse-power is attainable; speeds beyond this having the horse-power output reduced by centrifugal tension. Cotton ropes require less lubrication than do Manila ropes.

THE slab forging for the crankshaft of a 125-horsepower airplane engine weighs 605 lbs. The finished shaft weighs 46 lbs. The forging, of chrome-vanadium steel, costs over $200.00.

Brief Historical Sketch of Steam Boilermaking in Canada

By D. M. Medcalf *

The development taking place in our shipbuilding industry, more particularly that of steel construction, and the intimate relationship that exists between it and steam boiler building, make a retrospect of the associated crafts' achievement in Canada peculiarly opportune and interesting meantime. The article embodies the substance of an address delivered before the American Boilermakers' Association at their recent Annual Convention.

WHEN choosing this subject, I hoped to be able to obtain some assistance from the compilations of historians who have linked together the memories of past and present industries in Canada, but have been disappointed because they have overlooked the existence of the black squad who toiled in an unpretentious way, building steam boilers for our early industries. These horny-handed sons of toil appear to have passed away unhonoured and unsung, and their memories have been almost forgotten, save by a few of our old boilermakers and engineers. I have, therefore, decided that, rather than go into the details of construction in this paper, to treat the subject more in a general way.

Doubtless, the first boilermakers in Canada were located around the eastern seaboard. In the early part of the eighteenth century, settlements clung close to river, lake and sea, and the St. Lawrence, the St. John, and their tributaries, besides other lesser rivers, provided inevitably the points of settlement and the lines of travel. The development of water transport in Canada is interesting and furnishes a record of need, invention and enterprise, and not the least among these was the advent of commercially successful steam navigation.

Advent of Steam Navigation

First came the bark canoe, large enough to hold a few voyagers and peltry, and for a long time it held its place for the far journeys. For shorter travels, the canoe was superseded by the larger, but clumsier, bateau. In later years, the increase in river freight led to the introduction of the still larger Durham boats, whilst along the coast and on the great lakes the sailing schooner long filled a notable place. Finally the steamboat came in 1839. Only one year after the Clermont had begun its regular trips on the Hudson, there was built at Montreal the forty-ton steamer Accommodation, and seven years later the Frontenac, of about seven hundred and forty tons displacement, was launched.

It is noteworthy that the first steamship to cross the Atlantic without auxiliary aid was built in Montreal. This vessel was called the Royal William, and left Canada on the 5th August, 1833, for London, and arrived there about one month later. Our early Canadian boilermakers were, therefore, amongst those pioneers who not only developed water transport in Canada, but inaugurated ocean steam navigation. Marine boilers at that period were built rectangular in form of the marine flue type, carrying from 10 to 20 lbs. pressure. Boilers of this type, with certain modifications in design, were in vogue for a considerable time, and gradually developed into the Scotch marine type, with which we are all familiar. The development of these boilers was, of course, due to the efforts of Scotch engineers on the Clyde.

Boiler Types

With regard to the manufacture of boilers in Canada, around 1850, there were quite a few of the old pioneers engaged in this work. A list of names would perhaps be of little interest now,

D. M. MEDCALF.

but I mention the following firms who are still extant:—

E. Leonard & Sons, London, Ont., established 1839.

Waterous Engine Works Co., Brantford, Ont., established 1840.

John Inglis Co., Toronto, Ont., established 1859.

John McDougall, Caledonian Iron Works, Montreal, established 1858.

Goldie & McCulloch Co., Galt, Ont., established 1844.

Besides these, there was a large number of thriving little boiler businesses, long since petered out, like the Dicky Neal and John Perkins boiler works of Toronto, Joseph Hall, Oshawa, etc.

Pioneers in the Craft

In those early days, that is, sixty or seventy years ago, the types of boilers generally in use were externally fired with three to five flues, 8 to 10-in. diameter. There has been little development in this type of boiler, and the H. R. T. in use to-day is typical of the boiler used then. The diameter of these boilers seldom exceeded 54 inches, but what they lacked in girth, they made up in length, as twenty to twenty-five feet was no uncommon stretch for those old stagers. The seams were all of single-riveted, lap construction, and the plates ranged in thickness from ¼ in. to ⅜ in. The shell rings and also the tube rings were telescoped one into the other, like stove piping. They were very strong on domes at that time, and I believe a boilermaker then did not think he was building a boiler at all, unless he had a huge dome on the outfit. Most of these early domes were cast iron, and some of our manufacturers adhered to this style of dome until as late as 1890, in which connection I venture to say a good many explosions have resulted from these castings fracturing, two accidents of recent date coming under my own personal notice.

Materials of Construction

With the exception of the domes of some of these boilers, wrought iron was the material almost exclusively used in their construction. The brands of iron were Lowmoor, Yorkshire, Bowling, Thornycroft, etc., all imported from the British Isles. As a rule, the plates were short and measured about 4 ft. 6 in. square. These sheets were soft and ductile, but blisters or laminations were not infrequently met with, which caused considerable loss and inconvenience. Another imperfection was that of spongey parts, generally due to imperfect puddling, but, notwithstanding these defects, the old iron boilers gave good service, and we have many still in service, after thirty or forty years of general wear and tear. The majority of the boilers then were used in saw mills and flour mills, and were often employed to augment the power of a water wheel. The steam pressures carried were low, and forty to fifty pounds was looked upon as a very high pressure indeed. Fuel was cheap, as wood was plentiful, but coal was very scarce and seldom used, except by the blacksmith in the smithy fire, and the moulder in his cupola.

Our plate rolls were originally made of wood and were operated by hand. This, of course, was only made possible by the size and thickness of the sheets

*Chief Inspector of Steam Boilers, Province of Ontario.

used at that time. Punching was done by hand with a screw or bear punch, and sometimes as many as four men were employed at a time to pull on the punch lever. All holes were punched full size, and those that did not come fair enough were usually persuaded into alignment by the gentle assistance of drifts and sledges. Sometimes a taper reamer was used, but this was the exception, rather than the rule, and any holes which could not be reached with the punch were cut with a round-nosed chisel. The head plates were flanged with large wooden mauls over cast iron flange blocks of the required size. It was customary to make the heads a little undersize, so that they could be drawn out gradually to the exact diameter.

Heads were dished in a very crude manner by digging a hole in the ground, somewhat resembling the desired curvature of the head. The circular plate was then heated and beaten down into this hole with wooden mallets, the finishing process being accomplished by flatteners and sledge hammers. It sometimes happened in the case of heads dished to a deep camber that the work could not be done in this way, and a large cast-iron ball was often used to advantage. This ball was hoisted a certain distance, then dropped on the red-hot plate in much the same way as a pile driver.

These—what now appear to us—crude methods of the early boilermakers have undergone a vast change in the last fifty years. The up-to-date machinery now in use for every branch of this industry has almost entirely superseded hand work, and there is just reason to be proud of the modern steam boiler which our manufacturers are turning out to-day in large quantities. We must not, however, despise the useful work of our predecessors, for they built many good boilers in those good old days.

Boiler Inspection Feature

We have a large number of boilers in Ontario that were constructed before the present Act governing the construction of boilers came into force and took effect, which were built in a thorough workmanlike manner. We also have some that are not so good, and they were not all built in Canada, but since the enactment of the present law, we are quite satisfied that better boilers are now being turned out, and the purchaser is safeguarded as far as workmanship and material is concerned.

No matter how rigid the inspection, it is not a guarantee that the boiler will not explode, because it largely depends upon the care and attention the unit receives when in operation, how long it will remain in useful service. Quite recently, I was requested to make a personal examination of two 66 in. x 16 ft. H. R. T. boilers that had been seriously damaged. The boilers referred to were built from an approved design and inspected during construction; the shell plates were fabricated by one of the largest plate manufacturers in the United States, and were carefully examined before any work had commenced, the heat numbers and tensile strength recorded and passed as being suitable for a steam boiler. The workmanship was also examined during the entire construction, and upon completion, the boiler was passed, and certificates issued in the regular way. After these boilers had been in service six months, they each developed bags on the sheets directly over the fire, extending four inches down, three feet wide and five feet long, and on account of their being practically new, the owner claimed that the cause was poor material and workmanship, and I personally acted as a referee in the settlement.

When I visited the plant, and when trying to squeeze into the regulation inspector's outfit—which is now too small for me—I requested the owners to have the manhead under the tubes removed. The manhole in top of shell was open and ready for the inspector. Immediately the light was flashed on, the interior of the boiler, it was quite apparent what caused the trouble. The water that lay in the depression was covered with black spots, and the tubes and shell, as far as could be seen, were coated with oil.

It was at first a difficult matter to convince the owners that oil had caused the trouble; it was a new plant, and oil they claimed could not get into the boiler because they had installed an expensive oil separator in the exhaust line from the feed pump, which was the only steam line returning its condensation to the boilers. A further examination was made by disconnecting the oil separator, which was found quite clean, but beyond the outlet a full handful of grease was collected and shown to them, with the result that they were quite satisfied that they themselves were to blame, and not the poor manufacturer, who made the boilers to comply fully with the requirements of the Province of Ontario. The necessary repairs cost about $2,500 and considerable inconvenience to the operation of the plant.

I could cite a number of cases very similar to this one, but believe there is "nuf sed," and my object in mentioning this fact is because frequently when trouble develops, and the cause of same is not known, it is blamed on the rotten old boiler made by so and so, who is really blameless.

War Effect on Canadian Boiler Making.

Now, in regard to the effect of the war on the boiler-making industry in Canada, I might say that its penetrating influence has affected almost every industry we possess, either directly or indirectly, and the most seriously swayed of these have been engineering and allied trades. Almost since the beginning of the war, or, to be correct, since the Governments of the Allies began to place orders abroad for the supply of munitions, most of our boiler shops have been partly converted into munitions factories, whilst our machine shops are similarly engaged, running night and day.

Besides making shells, however, our boiler shops are turning out boilers in fairly large numbers, not only for domestic use, but for export trade, chiefly to the Allies, and we have orders for many more which cannot be supplied by reason of our inability to obtain the necessary material. It is true, therefore, that the war has increased the output of our boiler works, and it is also true that the war is retarding that output, owing to the scarcity of steel, or, to be correct, owing to this merchandise finding a more ready outlet in another channel; a large number of the mills, I believe, who are working on metals have sold their full production one year in advance for war purposes.

Dearth and Cost of Steel

The dearth of steel, however, is not the only obstacle. The price of steel, as you all know, has been going up with leaps and bounds since the war began. Labour conditions are also very bad, and good boiler makers to-day cannot be had in anything like sufficient numbers to cope with the increase in business. From the beginnig of 1915 to the present time, but more especially in 1915 and 1916, a large number of munition factories and like industries, which were urgently required to meet the existing crisis suddenly sprung into being, and consequently more boilers were required. Our manufacturers having only their usual stock of plates and tubes on hand were very soon unable to supply the goods until more material was forthcoming, and this occasioned much delay. Those factories, therefore, which urgently required boilers turned their attention to the second-hand market, and used boilers were largely sought after. Old boilers of all descriptions were painted up and offered for sale as good boilers, and, needless to say, many were condemned by our department. These scrap boilers have in turn found their way to the furnaces to be melted into shell billets, and latterly shipped to Germany via France. Perhaps a part of one of our old boilers, after undergoing this transformation, may yet find a resting place in the Kaiser or the Crown Prince.

The demand of late has not been so much for stationary boilers, as for marine boilers, and our manufacturers are harder pressed now than ever for steel plates and tubes, and, although they are turning out a lot of work, the demand by far exceeds the supply. If we only had steel plate mills of our own in Ontario, it would have been of great assistance at this period, but unfortunately we are not sufficiently advanced along those lines, and have to depend entirely on imported material.

Instead of Babbit Metals.—As a substitute for babbit metals an inventor proposes to use mixtures of metallic sulphides in widely varying proportions. He considers that the sulphides of copper, lead, tin and antimony make good babbitt substitutes. Metallic sodium is used to improve their casting properties.

It is not commercially possible to burn more than 99 per cent. of bituminous coal fed to the furnace.

High Pressure Air Compressor Design and Application*

By Joseph M. Ford

Compressed air at high pressure is becoming an increasingly important medium in modern engineering practice and in naval warfare. The accompanying paper deals with the machines which produce high pressure air, leaving on one side the question of power transmission by compressed air. In passing, the principal advantages of this system are referred to, and will be seen to be of considerable value. They consist of the facility with which energy can be stored; the unlimited rate at which accumulated energy may be converted into useful work; and, apart from loss of efficiency, leakage cannot cause any awkward consequences.

THROTTLING

IN a compressor which has its suction throttled, the volumes dealt with by the stages are of course reduced, which naturally involves a decrease in stage pressures. In a compressor with no cylinder clearances there would be no limit to the possible compression ratio in any cylinder; that is, the initial pressure in, say, the high-pressure cylinder could be very low and yet the machine would deliver air. In a cylinder with a large clearance, however, there is obviously a definite limit to the ratio of compression if air is to be delivered. If this ratio were exceeded, the air would simply be compressed into the clearance space and re-expanded. In other words, in order that the compressor shall deliver air, the intermediate-pressure delivery pressure must attain a definite figure, so that the total work is still divided between the stages, although not necessarily in correct proportion. The theoretical minimum initial pressure from which a cylinder can compress and just deliver (assuming no leakage) can be obtained from the equation:—

$$c\left[\left(\frac{P_1}{P_2}\right)^{\frac{1}{n}} - 1\right] = 1$$

where

c is the clearance ratio,

P_1 is the delivery pressure (lb. per sq. in. absolute),

P_2 is the minimum initial pressure (lb. per sq. in. absolute),

and

n is the exponent in PV^n=constant.

The above expression shows that P_2 increases as c is increased, and that with large clearances the compression ratio in any stage when the compressor is running throttled can be kept within limits, whereas in a machine having very small clearances the high-pressure compression ratio, with excessive throttling, might reach an abnormal figure, resulting in excessive temperatures in that cylinder. The foregoing would tend to show that a compressor with good clearance volumes is preferable to one with small clearances, and for some Diesel engines — especially those of the marine type, where the conditions under which the compressor works may vary between fairly wide limits—this is the case.

As previously mentioned, clearance results in a reduction in the effective capacity of a cylinder, so that larger cylinders must be fitted than would be necessary with no clearance volume. The direct result is an increase in the piston loads. For example, a compressor of 300 cub. ft. per minute displacement at 350 r.p.m., having stage pressures of 45 and 300 lb. per square inch, when working at 900 lb. per square inch delivery pressure, and cylinder clearances for low pressure, intermediate pressure and high pressure of 4, 5 and 10 per cent. respectively, has a maximum air load on the high-pressure piston of about 7,900 lb., whilst the maximum intermediate pressure piston load is 14,300 lb. In a similar machine having, however, low pressure, intermediate pressure and high pressure clearances of 4, 15 and 30 per cent. respectively, the high-pressure piston load is increased to 12,100 lb. and the intermediate pressure load to 22,800 lb. Figs. 12 and 13 give for various clearance ratios the maximum piston loads for compressors of the above capacity and stage pressures.

B—For a machine with clearance volumes—L.P. 4 per cent., I.P. 15 per cent., H.P. 30 per cent. fo volume swept. Final delivery period, black; re-expansion of clearance air, single hatching; suction from intercoolers, circular hatching; transfer periods, cross hatching; compression periods, blank. The diagram from the L.P. points will be practically identical for the two machines, and is therefore not given.

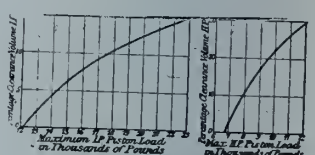

FIG. 12. FIG. 13.

Diagram showing effect of clearances on piston loads for a given output at a given pressure.

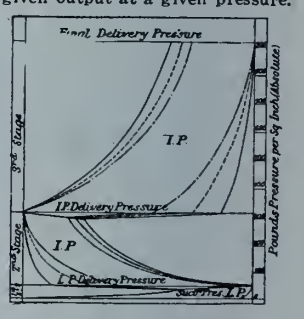

FIG. 14.

Combined diagrams for three machines designed for same output and stage pressures.
For a machine with clearance volumes—L.P. 4 per cent., I.P. 5 per cent., H.P. 10 per cent. of volume swept by piston.
For a machine with clearance volumes—L.P. 4 per cent., I.P. 10 per cent., H.P. 20 per cent. of volume swept by piston.
For a machine with clearance volumes—L.P. 4 per cent., I.P. 15 per cent., H.P. 30 per cent. of volume swept by piston.

Fig. 14 shows the combined indicator diagrams for three machines, whose pressure characteristics are shown in Figs. 12 and 13. Inspection of the diagrams super-imposed shows that as the clearance is increased the commencement of delivery and the commencement of suction, in both the intermediate-pressure and high-pressure cylinders, occur later in the stroke. With a large clearance, therefore, the maximum cylinder load is not attained until the crank is at a somewhat smaller angle from the dead centre than would be the case in a machine with no clearances, due to the fact that the actual compression takes place during a longer portion of the stroke, and further, the re-expansion of the greater volume of clearance air occupies a larger portion of the stroke, so that the pressure acting on the piston does work on the crank through a greater angle than it would were the cylinder clearances small. The crosshead load (neglecting inertia and weights of parts) at any point in the stroke, for the particular type of machine under consideration, is the difference between the intermediate-pressure piston load acting upwards and the low-pressure and high-pressure loads acting downwards, so that with the increased clearances the greater loads in the high-

*Part II. of a paper read before the Greenock (Scotland) Association of Shipbuilders and Engineers.

pressure and intermediate-pressure cylinders tend to balance one another to some extent. The result of this is that although the actual piston loads are considerably increased with large clearances, yet the maximum turning moment is augmented to a much less extent.

Fig. 15 gives the turning moment diagrams for two of the three compressors previously mentioned, namely, that with the 10 per cent. high-pressure clearance and that with the 30 per cent. high-pressure clearance. It will be seen that the maximum value occurs in this case when the crank is about 65 deg. from top centre. The comparatively small increase in maximum turning moment with the larger clearance, compared with the increase in the actual piston loads, is to be noted. The effect of the increased clearance volumes on the crank angles at which the various events of the cycle occur is also clearly seen.

Fixing of Stage Proportions

When a machine is required to deliver a given quantity of air at a given pressure, one of the first decisions concerns the number of stages in which the compression should be effected. The main factors are: the initial cost of the machine, reliability and economy in operation, and safety in operation.

The initial outlay increases as the stages are multiplied. With a small machine the gain in economy and safety in operation due to increasing the number of stages is of less importance than in a large one. Cooling will be more effective due to the smaller cylinders, and the castings will probably be more reliable, thus lessening the chances of breakdowns. In addition, piston leakage in a small two-stage machine will probably be much less than in a three-stage machine of similar capacity, because in the former there will only be leakage past two sets of rings, whereas in the latter there are three sets. Moreover, the high-pressure piston in the two-stage compressor will obviously be larger than that of the three-stage one, so that the piston rings are much more likely to be air-tight. It is a recognized fact that in practice small rings, in spite of the smaller circumference, are more difficult to make tight than large ones.

The necessity for reliability demands, for reasons previously mentioned, that the temperatures in the cylinders be kept as low as possible, which in large machines, where the cooling is comparatively poor, demands division of the compression into several stages.

An important point in the computation of stage proportions is to arrange as far as possible for equal temperatures in each stage, for then the highest temperature is a minimum. Theoretically, this can be attained by dividing the work equally between the stages—which also results in the minimum of work required per unit of air compressed. In practice this is only true when the cooling effect is the same for all stages and the intercooling perfect.

Fig. 16 shows the theoretical theta-phi diagram for a three-stage compressor delivering air at 900 lb. per square inch gauge pressure. With equal division of work between the stages and intercooling down to the initial atmospheric temperature, the heat equivalent of the work required per lb. of air is represented by the area under ABHMPGR down to the line of absolute zero temperature (diagonal shading). The cooling effect is assumed to be the same for all stages, and as a result it will be seen that the miximum temperatures attained are the same for each stage of compression., 260 deg. F. The distance a, b, and c are, of course, equal, since the compression ratios of the stages are identical.

Supposing that, owing to restricted water supply, climatic conditions, or circumstances connected with the design of the machine, it is found that in the first stage intercooler the air can only be reduced in temperature to 90 deg., and in the second stage intercooler to 120 deg., then the diagram is modified as shown by the dotted lines. The heat equivalent of the work required per lb. of air will then be represented by the area under ADJLOGR down to the line of absolute zero temperature, the excess over the previous case being represented by the horizontally shaded portions. The temperatures attained in the stages are no longer equal, but increase towards the final delivery. In this case they are: low pressure = 260 deg., intermediate pressure = 300 deg., high pressure = 340 deg. The compression ratios of the stages are, however, still equal.

With the poor intercooling, even, the maximum temperature of the cycle can be reduced by changing the distribution of work between the stages.

If the compression ratios in the various stages are made in the proportion x : y : z (see Fig. 16), then the stage temperatures will be the same, and consequently a minimum, although the intercooling is bad and the work distribution unequal.

The modification to the temperature-entropy diagram for these latter conditions is indicated by the chain-dotted lines, and the work in this case is the area under ACFKNER down to the absolute zero of temperature line. This is found to be slightly less than that required for the previous case, in which the compression ratios were equal. In some cases, therefore, better results are obtained from an unequal distribution of work than would be the case were each stage given an equal share, and also it may be pointed out that probably more valve trouble results from excessive temperature than from any other cause.

The design of certain machines is such that the cooling in some stages is likely to be very much better than that in others, in which case the work in the well cooled stages can be increased, and thereby relieve to some extent the stages with inefficient cooling.

Fig. 17 shows approximately the entropy diagram which would be obtained from a test on one of the machines previously referred to, namely, that with the low-pressure clearance 4 per cent., intermediate-pressure 15 per cent., and high-pressure 30 per cent. of the piston displacement.

It is not proposed to enter into the question of the application of the theta-phi diagram to air compression. The peculiar shape of the lines representing the change from the initial condition to the final condition at end of compression is due to the transfer of heat from the cylinder walls after compression has commenced and to the heat added to the air as a result of piston friction. The deviation to the right of the vertical indicates that the air temperature is rising even faster than with adiabatic compression as a result of the addition of the said heat. Later on in the stroke cooling sets in and the compression becomes further removed from the adiabatic, shown by the line bending over to the left.

The atmospheric temperature is assumed to be 60 deg. F. The point "X" represents the initial condition of the air in the low-pressure cylinder just before compression begins, and it will be observed that the temperature has been increased by the amount delta t_1 (in this case 20 deg.), the increase being due to the fact that the air on its way to the cylinder has become heated through contact with hot valves, etc. In this particular case, with a mechanically controlled suction valve, the initial pressure is seen to be very slightly above 14.7 lb. per square inch, due to the inertia of the moving column of air in the suction pipe.

The first stage compression is carried to 59.7 lb. per square inch absolute and the temperature rises to 320 deg. F., the large rise being due to the fact that cooling is rather bad in this stage, partly as a result of a large portion of the "cover" being occupied by the high-pressure cylinder and the rest by large delivery valves, so that cooling cannot well be applied to this part. From the diagram it will be seen that the resultant compression is almost adiabatic.

After the first stage of compression the air is cooled in the intercooler to 80 deg. F., but on entering the second stage cylinder it again increases in temperature delta t_2 due to the hot piston, passages, etc., and also as a result of mixing with the re-expanded clearance air. The restriction in the intercooler tubes and in the valves results in a pressure drop, so that the initial second stage pressure is somewhat lower than the low pressure delivery pressure.

The total effect, then, of the above is that the initial condition in the second stage cylinder is represented by point "Y" in stead of point "J," as would be expected.

It is assumed that the large clearance space in the intermediate-pressure cylinder is well cooled, and this, together with the good packeting effect, results in the compression being further removed from the adiabatic than it is in the low-pressure cylinder, so that in spite of the considerably greater share of the work done by the intermediate-pressure, the temperature of compression is not very much in excess of that in the previous stage. A similar sequence of events takes place in the high-pressure cylinder, where, again,

owing to the large well-cooled clearance, compression is within the adiabatic. This, together with the fact that the high-pressure stage has the smallest share of the work to do, results in the comparatively low final temperature of 240 deg. F.

Even with a poor distribution of work, as in this case, the temperatures need not necessarily be excessive. There are, however, other aspects of the problem of determining stage proportions. Consider the case of a high-speed Diesel engine compressor, where it is desirable that the balance and twisting moment diagram of the machine should be as good as practicable, in order as far as possible to eliminate vibration.

With a machine of a certain type, it will be obvious that the crosshead load at the top centre will be due to both the low-pressure and high-pressure delivery pressures on their respective pistons, whilst at the bottom centre the load is only that due to the intermediate-pressure pressure. The maximum upwards load is then about twice the maximum downwards load, which would not conduce to the best running.

There are two ways of bettering conditions, one of which is to retain the stage pressures and adjust the intermediate pressure clearance until the load approximates to that desired (see Figs. 12 and 13), and the other is to choose the stage pressures so that the upload is reduced and the down load increased. Increased down loads necessitate larger connecting rod bolts, which in some cases, on account of the restricted space available, might not be easily accommodated.

Provision for Variable Delivery Pressures and Volumes

Another consideration when fixing stage proportions is the possibility of the machine being run at delivery pressures higher than normal.

In the remarks on clearance this question was mentioned, and the advantages of large clearances in this connection were enumerated.

The loads to which large clearances give rise (Figs. 12 and 13) might be inadmissible for various reasons, whilst the increased cost due to the larger cylinders might be a disadvantage, so that the constant proportional division of work between the stages, almost always approximately possible of attainment by choosing suitable clearances, would not in this case be secured.

If the machine runs at a pressure above its normal the division of work will be upset, and the high-pressure stage will take a considerably increased share of the total load, which may result, among other things, in an undue rise of final delivery temperature. If this latter is reasonably low when the machine is working at normal pressure, the rise due to the increased pressure will not be of such great consequence. To meet these conditions it is usual to arrange that the high-pressure stage shall, under normal conditions, take rather less than its proper share of the total work. The temperature in the other stages will be somewhat increased, but the rise in these temperatures due to the small increase in pressures as a result of the greater delivery pressure is inconsiderable.

If the machine has to run throttled in order to reduce the volume delivered, then it is again desirable, if possible, to arrange that the high-pressure stage shall under normal conditions take the smallest share of the work, since throttling reduces the stage pressures without altering the delivery pressure, thereby resulting in an increased high-pressure delivery temperature.

The importance of keeping the high-pressure temperatures low may again be emphasized. Burning and explosion of the lubricating oil here is of great violence when it does occur, which happily is very rare, due, among other things, to the attention given to the selection of the oil itself.

Volumetric Efficiency

One other point which arises in connection with the determination of stage proportions is the question of the volumetric efficiency of the low-pressure cylinder. If the low pressure stage is given a large share of the work, the effective capacity of the machine will be less than it would be with a lower first stage delivery pressure for reasons explained in the notes on the effect of clearance.

From the above it will be seen that multistage compressor design is to a large extent a matter of compromise. Each case should be treated by itself according to the duty of the machine and conditions under which it is to be run, and the best combination under the circumstances of loads, balance, and temperatures should be found, whilst the behaviour when throttler or running at various pressures must also be considered.

The question of cost should not be forgotten, for in some cases the advantages gained by, say, adding clearance, and thereby increasing cylinder sizes, may not warrant the additional expenditure.

Cylinder Proportions

Fig. 18 shows the stage pressures adopted in some of the very latest three-stage compressors for Diesel engines, by four different British and Continental builders, and bears out the remarks regarding the compromise in design of compressor.

Having decided on the stage pressures and cylinder clearance ratios, the actual determination of main dimensions is relatively simple.

When fixing the cylinder sizes, the low-pressure cylinder is settled first, as in a steam engine. A low-pressure delivery pressure is assumed—basing the assumption on previous practice if available—and from this pressure and the clearance volume in the cylinder (depending largely upon the type of valves used) the indicated volumetric efficiency is calculated. The dimensions of the cylinder are chosen such that, after the clearance air has re-expanded, the cylinder can draw in the required amount of air, plus an allowance for leakage through the compressor. Regard should also be paid to the fact that the air on its way to the cylinder, through contact with hot valves, passages, etc., becomes heated—which reduces the actual weight of air dealt with.

Where the workmanship is of the first order, about 85 to 90 per cent. of the air actually taken into the compressor will be delivered when compressing to 1,000 lb. per square inch in three stages.

The second stage cylinder is proportioned so that after its clearance air has expanded it can contain the whole of the air delivered by the low pressure at the low-pressure delivery pressure, and at the temperature resultant upon the mixing of the incoming and the clearance air. Attention should again be given to the effect of the hot cylinder cover, piston,

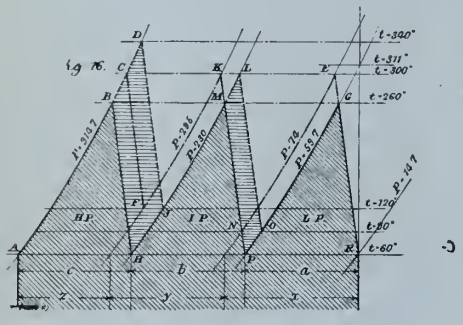

FIG. 16.

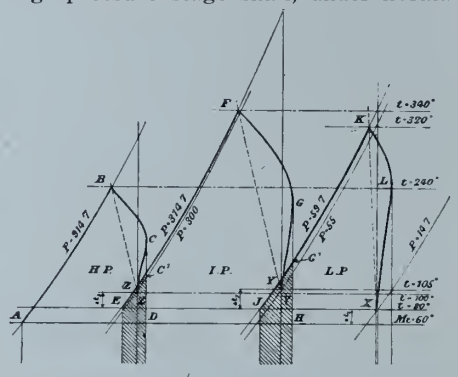

FIG. 18.

This chart may also be used to determine the ideal stage pressure (i.e. equal compressions per stage for compression to pressures up to 1,000 lbs. per sq. inch in 2 or 3 stages. For 3 stages of compression a line from the zero point to the intersection of the delivery pressure line and vertical H.P. cuts the other verticals in the ideal pressures. Example:—3-stage compression to 500 lbs. per sq. inch gives—L.P. pressure = 33 lbs. per sq. inch, and I.P. pressure = 142 lbs. per sq. inch gauge. For 2-stage compression join zero point to intersection of delivery pressure line and vertical I.P. The L.P. pressure can then be read off as before.

FIG. 17.

etc. The other stages are similarly treated.

Experience is an important factor in the settling of cylinder proportions, as in the higher stages, at any rate, it is essential that allowance be made for leakage. For example, in a four-stage machine compressing to 3,500 lb. per square inch, possibly not more than 80 per cent. of the air taken in ever reaches the high-pressure cylinder. If this cylinder is made big enough to deal with the whole of the air aspired by the machine, it would actually take considerably more than its intended share of the load.

One method of finding the volumes of the various cylinders is the "constant weight" method, which depends on the fact that (neglecting leakage) the weight of air in all the cylinders at the end of the suction stroke is the same, correction for leakage being made afterwards. Another method, which can be used graphically, is the "equivalent cylinder" method. Here the volumes of the ideal cylinders with no clearance are found, assuming the compression isothermal, and an adjustment is then made for the effect of clearance air and temperature rises.

When the cylinder sizes have been determined, the size, location and number of valves may be fixed, determining to a great extent the way in which the necessary clearance volume is made up.

Small deviations are often made from the theoretical figures for reasons of manufacture. Supposing that the calculated high-pressure cylinder diameter was 3⅜ in., for convenience of manufacture this dimension might possibly be made the more even figure of 3½ in., entailing, however, an increase of 7½ per cent. in the volume. Some builders, however, work to sixteenths of an inch in cylinder diameters.

Modern Multi-Stage Compressor Practice

Comparison with Steam Engines.—The care and consideration which must be given to the question of proportioning a compressor is probably of more importance then that required for, say, steam engine design, in addition to which the engineering practice for the successful construction of compressors must be of the highest order. In the case of a triple marine engine, the cylinder clearance volumes are of comparatively small importance, and the arrangement of the engine need not be altered to suit the clearances. Should the distribution of work be less even than as designed, it is only necessary to alter the cut-off in the different cylinders. The work done by the high-pressure cylinder can readily be reduced by cutting off earlier in the medium-pressure cylinder, but in an air compressor reduction of the high-pressure work entails the addition of clearance volume to the high-pressure cylinder, which addition it is usually almost impossible to effect.

Small errors in the calculation of steam engine design have sometimes been corrected by the introduction of packing pieces, or stepped keys in the valve gear, but with a compressor it is rarely possible to correct mistakes. The workmanship must be of the highest class, especially with such details as valves and high-pressure plungers. Piston rings and cylinder bores also call for particular attention.

A noteworthy difference between steam engine and compressor design is that, whereas with the great majority of steam engines the cylinders are double-acting, in high-pressure compressor work they are invariably single-acting in the generally accepted sense of the term. Another difference is the very frequent use of differential pistons, which are rarely met with in steam engines. These points give rise to a large number of possible arrangements of compressor cylinders, a few of which are shown diagrammatically in Figs. 19 to 29.

Cylinder Arrangements — Fig. 19 shows the most common arrangement of a three-stage compressor. On the down stroke air is drawn into the space marked low pressure through the suction valve, having previously passed through a silencer. On the up stroke this air is compressed, and delivered through the first stage intercooler to the annular space marked intermediate pressure, where, on the next down stroke, the second stage of compression is effected. The air is again cooled in an intercooler before passing to the high-pressure cylinder, where the final compression is carried out. Before the air is delivered to the storage bottles it is customary to pass it through an aftercooler (consisting usually of a submerged pipe), in order that the air in bottles shall not become unduly heated. This compressor arrangement is largely adopted on Diesel engines, as well as for independent plants on account of its comparative simplicity and compactness, but it has several disadvantages.

To examine or renew new-pressure or intermediate-pressure piston rings, it is generally necessary to lift the whole piston and connecting rod up through the cylinders before the gudgeon pin can be removed, which in some cases, such as in submarine engines, is an undesirable feature on account of the limited head-room usually available. It may also be noted that the low-pressure and intermediate-pressure work is all done in the same cylinder, as it were, so that more heat has to pass through the cylinder walls to the jacket than would be the case were an

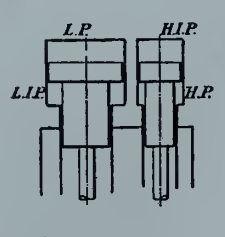

FIG. 29.

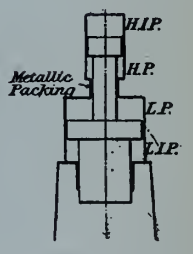

entirely separate cylinder devoted to each stage of compression. This, however, in practice is not of much moment.

Fig. 20 shows a small two-crank machine suitable for a motor-driven plant. With this type of machine the working parts are in constant thrust. A modification of this last arrangement is shown in Fig. 21, where both lines are driven by the same crank. This "V" compressor has been used on several marine Diesel engines, where the effect of the uneven turning moment resulting from this design is of but slight importance. It may be added that the angle of the "V" is usually somewhat less than that shown diagrammatically in the figure.

A curious adaptation of the type shown in Fig. 19 is given in Fig. 22. This arrangement, although expensive, has been used on some of the largest high-speed Diesel engines yet constructed, and is very satisfactory in operation. Instead of employing a single compressor, two entirely separate small machines are used, actuated from the ends of a rocking lever driven from the crank shaft by means of a single connecting rod.

A great advantage gained is a reduction in the size of cylinders necessary, which results in a marked improvement in the cooling and reliability. In addition, the turning moment of the combination is good, whilst the side thrust on the pistons resulting from the obliquity of the connecting rod in the usual design is, in this case, almost entirely absent.. Another minor point to which attention may be directed is, that if a compressor valve breaks on, say, the starboard engine in a ship with this arrangement, only 25 per cent. of the main engine air supply is stopped, instead of half, as would be the case were each main engine fitted with a single compressor. As a result, it is quite likely that it would be found possible to carry on without running a big auxiliary compressor, which in many cases, being motor driven, entails the operation of a large generator set. Fig. 23 shows the arrangement occasionally adopted for Diesel engine work. Its obvious feature is its simplicity.

An arrangement which has been employed in one or two instances is shown diagrammatically in Fig. 24. Here the high-pressure stage is entirely separate from the other cylinders, and is driven by means of rocking levers. Accessibility is a feature of this design. To remove the intermediate-pressure piston it is only necessary to lift the intermediate-pressure cylinder cover and take off the nut securing the piston to the rod. By lifting the intermediate-pressure cylinder a little, it will now be a simple matter to withdraw the low-pressure piston. The high-pressure piston is easily withdrawn by putting the crank on top centre and uncoupling the link between the levers and piston. Note that the first stage of compression is effected on the under side of the low-pressure piston. This means that the heat from the intermediate pressure is well removed from the heat of the low pressure, so that the cooling is more efficient. The air in the space between the low-pressure and intermediate-pressure pistons is simply compressed on the up stroke, and re-expands on the down stroke—a relief valve being provided to guard against excessive pressurt due to piston ring leakage.

Fig. 25 gives another arrangement of compressor suitable for a Diesel engine, where the air displaced by the idle side of the low-pressure piston is passed to the idle side of the intermediate-pressure piston in a similar manner to the previous case.

In the arrangement shown in Fig. 26 each side of the large piston does a part of the first stage of compression, whilst the second stage is effected in a cylinder at the bottom, as shown. This necessitates the use of a gland subjected to a pressure of perhaps 300 lbs. per square inch as well as a high temperature, but this is of minor importance. The up and down loads are more nearly equal than is the case with the usual arrangement, and, in addition, the maximum crosshead load for a given capacity is reduced as a result of the decreased low-pressure piston diameter. It may be mentioned that this arrangement is adopted in one of the largest compressors yet built for Deisel engine work.

Figs. 27 and 28 show arrangements of four-stage compressors, suitable for torpedo air compressors. The former design necessitates glands, but permits of rather better cooling than the latter, which, however, has an advantage in that crossheads may be dispensed with if required.

A single-line four-stage arrangement is shown in Fig. 29, but this suffers somewhat from lack of accessibility, although the loads up and down can be equalized, as two stages of compression are carried out on each stroke. There are other arrangements to suit various conditions as to accessibility, compactness, balance, etc.

Cylinders and Piston Packing

The conditions under which compressor pistons run are different from those in a steam cylinder, where there is generally a certain amount of condensation and the water so formed acts as packing in an effective manner. In a compressor a little moisture from the atmosphere is present, but this is generally insufficient to permit of using, for instance, solid piston valves, as sometimes met with in steam practice. Special attention should be given to the question of piston packing, which, however perfect, is useless unless the cylinder bore is machined to within extremely fine limits, the required accuracy being greater the higher the pressure which has to be withstood. In the case of high-pressure cylinders opinion is divided as to the best means of producing the nearest approximation to the perfect bore. Some builders finish the bore by an elaborate system of reamers, and the accuracy and uniformity of the bore so produced leave little to be desired. Other manufacturers pin their faith to grinding methods, and in many cases the bore is lapped out to size. The packing used on high-pressure pistons is varied. For machines such as those used for torpedo charging, which only run intermittently, leather or some patent packing of a similar nature is used. Any slight unevenness in the bore or lack of alignment is taken up easily, and the leakage is very small. The question of temperature should not be overlooked, for if these are too high, burning of the packing will result, and in some cases, to reduce the possibility of this as far as possible, cylinder lubrication is effected by means of a comparatively copious supply of soap-water, oil being used but sparingly.

In compressors for pressures above 2,500 lbs. per square inch it is almost universal to find leather or similar high-pressure packing, and very frequently arrangements are made for introducing a certain amount of distilled water with the suction air. There are two ways of fixing the packing, one of which is to carry it on the piston, in the same way as piston rings, and the other is to use it in a similar method to that usually adopted with hydraulic machinery — the particular method adopted depending on the arrangement of the compressor.

For a Diesel engine compressor, or any machine which has to run at full load for long periods at a time, leather is not sufficiently durable, and recourse is made to metallic packing, consisting generally of piston rings. These rings are usually made of selected cast iron, and may be of the ordinary "Ramsbottom" or other types. Some builders adopt rather elaborate packing systems for high-pressure pistons which have special properties, such as being adjustable for axial wear and being self-aligning, whilst others use plain cast-iron rings with almost equally good results.

One point in this connection which may be mentioned is that "air packing" should never be adopted with high-pressure pistons, since the high-pressure air forces out the ring against the cylinder wall, and whilst giving a splendid result as far as air-tightness is concerned, increases the wear of the cylinder. Occasionally metallic packing is used in a type of gland, with, in some cases, satisfactory results. The packing may be of the manufactured ring form, or may be shredded white metal and graphite.

Regarding the other cylinders of the compressor, equal attention should be paid to the bores as with the high-pressure cylinder. The piston packing adopted consists usually of cast-iron rings, although some manufacturers fit leather or similar packing throughout the machine. For glands under air pressure, metallic packing is preferable, as the majority of the usual packings quickly deteriorate under the dry heat to which they are subjected.

Valves

The question of the design of valves for an air compressor is one which demands careful thought and attention, for no other part is so vital to the proper working of the machine. The type of valve used in all high-pressure compressors is the automatic valve, which depends for its action on a difference of pressure above and below it, and is not actuated by any external means. This appears in countless forms, but of few can it be said that they are entirely satisfactory.

Automatic valves are essentially of a more or less delicate construction, and the conditions under which they operate are usually severe. The delivery valves have to pass air at very high temperatures, and the heat, unlike that in a steam engine, is a dry heat; whilst in a high-speed machine running at, say, 450 r.p.m., the valves have to lift and seat themselves in a very short space of time.

For example, in a low-pressure cylinder in which compression is carried to 80 lb. per square inch gauge, at 450 r.p.m. the delivery valves have to open, pass the air, and completely seat themselves again in a period which is actually less than one-sixtieth part of a second. In order that this operation shall be successfully accomplished, either a powerful spring must be used to reseat the valve, or else the lift must be exceedingly small. The result of using a strong spring is that the pressure required to open the valve is excessive, and the hammering of the valve on its seat under the influence of the spring results in very rapid wear. The alternative, namely, the adoption of a small lift, means that the diameter of the seat must be large in order to obtain the requisite area through the valve for the flow of air. It may be stated that velocities in practice through the valve may be 130 ft. per second for low-pressure valves, and may be 250 ft. per second for high-pressure valves. If the diameter of the seat is increased over that sufficient with a larger lift, the leakage is increased, owing to the larger circumference of the contact circle; and, moreover, since a large valve is more liable to heat distortion than a small one, the possibilities of leakage are still greater.

Whatever the diameter of the valve, the weight should in every case be brought to the minimum. This reduces the inertia forces, and thereby the spring strength. Consequently the wear due to hammering and excess pressure required to open the valve is decreased. The type of valve usually employed for high-pressure work is the thimble valve, which can be used either for suction or delivery, two or more being used per cylinder to obtain the necessary area of flow. The valves proper are usually of nickel steel, and the seats of best quality bronze or gun-metal, although one Diesel engine builder used to fit valves in small compressors with seats of ebony or lignum vitæ. The actual seat should be as narrow as possible, in order that the unbalanced load may be reduced to a minimum.

For moderately high pressures small valves of the well-known plate type are frequently used. The plate is usually of special steel and the seat of bronze. It has been found in practice that this type of valve, at any rate in the larger sizes, is liable to fracture if the lift is too great, so that, in order to obtain sufficient area for the passage of the air and at the same time keep down the diameter, it is necessary to adopt multiple seats and to cut ports in the valve for the exit of a part of the air. Given suitable conditions, this type of valve when properly designed and made is superior to the thimble or poppet type, especially for the low-pressure stage, but the plates are somewhat unreliable when the temperature is excessive. One advantage over the other type is that carbonisation has very little effect on the working.

A type of valve to which one prominent Continental firm have pinned their faith is the "Gutermuth" valve, which consists essentially of a strip of steel wrapped round a spindle in a similar manner to a clock spring. This has been used with great success in all the stages of Diesel engine compressors up to quite large sizes.

In high-pressure compressor work the valves must be kept in thoroughly good condition, as otherwise a leakage may take place from any stage to a lower one, thus increasing the pressure and temperature attained in the latter. This would upset the balance, and in extreme cases cause a serious breakdown by adding, perhaps, 250 per cent. to the load on the connecting rod bolts. To guard against such contingencies it is of the utmost importance that ample relief valves be fitted to all stages, and however reliable a machine may appear to be, it is dangerous to run with the relief valves out of action.

It is not proposed to deal with mechanically moved valves, as their application to high-pressure compressor work is limited, usually to the low-pressure suction, with perhaps the addition of the intermediate-pressure suction. The great advantage of a mechanical suction valve for the low pressure is that one can ensure that the cylinder is filled with air at atmospheric pressure, instead of at a lower pressure due to the attenuation consequent upon a spring-loaded suction valve. If this mechanical valve is arranged in the piston itself, as is done in some designs, the cylinder clearance volume can be appreciably reduced. The delivery valves are invariably automatic. A valve gear which would adapt itself to the varying point of delivery with different pressures would obviously be somewhat complex. In high pressure work the necessity for this refinement is rather doubtful.

Regarding the disposition of valves, these are usually arranged in the cover of low-pressure cylinders in order to reduce clearance as far as possible, thereby seriously detracting from the cooling surface. Suction valves in the piston are not without disadvantages, since at the end of the suction stroke the inertia of the valve tends to seat it too soon and the cylinder is not fully filled with air. In some cases this arrangement necessitates the suction air being drawn through the crank case. It is argued that this tends to keep the running parts cool, but this is a doubtful advantage when it is remembered that the low-pressure compression starts with air which has been already heated, and is probably charged with oil vapor.

COOLING POWER OF A REFRIGERATING MACHINE

THE cooling power of a refrigerating machine is based and calculated on a continuous run of 24 hours per day. If, therefore, a machine is specified of 24 tons cooling capacity, it will have to run continuously for 24 hours to accomplish this amount of work. During one hour's operation, the machine will only give a cooling effect of one ton. If a certain amount of work is required to be done in 12 hours the capacity of the machine must be double that required to do the work in 24 hours.

All refrigerating machines are rated or specified of so many tons cooling capacity or, in other words, are equal to so many tons of ice melting. As a ton of ice when melting gives off 284,000 B.t.u. at a temperature of 32 degs. Fah., a refrigerating capacity of one ton is, therefore, equal to 284,000 B.t.u. with a brine temperature of 32 degs. Fah. By B.t.u., or British thermal unit, is meant the power to cool one pound of water one degree, or what is the same, 1-10 of a pound. 10 degrees.

The refrigerating capacity of a compressor depends on the weight of the ammonia gas circulated per 24 hours. As the weight of the ammonia gas as well as the temperature depends on the pressure, that it to say, as the weight and temperature of the gas rises or falls with the pressure, it follows that the higher the refrigerating temperature the greater will be the work that the compressor will accomplish, and the lower the refrigerating temperature, the less work the compressor can do. This is the reason that in cold stores the amount of compressor power required to keep temperatures of zero in the rooms is more than double that required to keep the temperature at, say 30 degs. Fah.

CONCERNING BELTS

EXPERIENCE has shown that a long belt, other things being equal, will transmit more power and last longer than a short one. It is easy to remember that a belt one inch wide, travelling 800 feet per minute, and with suitable tension, will transmit one horse-power. If the same belt travels 1600 feet per minute, or if the 800 feet belt is 2 inches wide, both will transmit two horse-power, and so, for every extra inch of width, or an additional speed of 800 feet per minute, an extra horse-power will be procured. If a belt is laced too tightly there will be no fault in its driving, but the journals of the shafts that carry the pulleys will have too much to do, and will soon wear out. If a belt is laced too much on the slack side-slipping will take place, and extensive friction on large cast pulleys has been known to generate sufficient heat to crack the pulleys, even to cause them to burst and fly about and kill. A horizontal belt of considerable length and laced only just tight enough is an ideal drive. Between this ideal drive to the worst, i.e., a vertical drive with a short belt, there are many gradations, but so long as one always visualises the ideal and the worst, care will always be taken when arranging drives to approach the former and ignore the latter.

Electricity and Hydraulics

BRUSHES FOR COMMUTATORS AND SLID RINGS*

IN the selection of brushes for commutators and slip rings there are several important governing factors. Among those of ranking importance are the following:—

1—The brush should possess such characteristics as will enable it to carry the maximum current to be transmitted by it. This maximum current consists of two factors for either direct-current or alternating-current use, viz.:—

(a)—The kilowatt load or working current of the machine, whether direct or alternating.

(b)—The short-circuiting current between the bars being commutated in direct-current service, and the magnetizing currents due to power factors above or below unity in alternating current service.

The kilowatt load or working current is readily measured or determined in terms of either direct current or alternating current and for alternating-current service the magnetizing, wattless or idle currents can also be definitely measured or calculated. The short-circuiting current under the brush, however, is a very indefinite factor and may have values ranging from approximately zero in a machine having ideal commutating characteristics to values in excess of the load or metered current in machines having poor commutating characteristics. Brushes, therefore, may be, and generally are, subjected to loads greatly in excess of the load, or kilowatt, current.

Anent the short-circuiting current under the brush:—A direct-current, non-commutating pole generator was designed for, and sold with, a given rating, the rating being in excess of the immediate demands. As the demands increased, armature temperatures became abnormal and commutating troubles expanded. It was impossible to commutate within many kilowatts of the name-plate rating. A local concern proposed to make the machine deliver its full-load rating for a given sum, with the further understanding that a bonus of so much per kilowatt was to be paid for each kilowatt output in excess of the machine's one hundred per cent. rated capacity. In the event of failure no money was to be paid. The proposition being accepted, several modifications were resorted to, the principal one being that of "trimming" or "beveling" the poles. In time the machine was groomed for the bonus; the test followed—also a failure. The machine not only failed to deliver its full-load rating, but persisted in dangerous temperatures. A friendly engineer was consulted, who with a flight of surprising intelligence for a man of his profession, suggested that the brushes be slotted, parallel with the commutator bars, and to a depth of an inch or more. The output jumped; temperatures dropped; the repair concern collected its bill, plus a bonus, and the friendly engineer stood modestly by, with satisfaction for his portion. This is not a fanciful sketch, but a fact, and illustrates the unknown which is taking place to a greater or less degree under all commutating brushes.

2—The brush should be homogeneous, i.e., it should be uniform in material, mixture and hardness (free from hard and soft spots.)

3—Brushes for either alternating or direct-current use should be self-lubricating. Experience shows, however, that the vast majority of brushes require lubrication. In many instances brushes are "treated" by the makers, i.e., they are impregnated with certain lubricating oils, greases, or compounds, in order to make them self-lubricating, or as nearly self-lubricating as possible. Generally speaking, the permanency of such treatment is problematical, inasmuch as the lubrication frequently volatilizes , or drains from the brushes, leaving the brush practically, if not entirely, in its dry state.

4—For undercut commutators the brush material should be entirely, or to a great degree, free of abrasive (that is, of certain cutting compounds or mixings which are added to the brush material to scour or polish), or the commutator will wear too fast, bridge the slots. necessitate frequent beveling of the bars, repeated undercutting and constant cleaning.

5—For smooth commutators with soft mica a larger percentage of abrasive is desirable than in brushes for undercut mica.

6—For smooth commutators with hard mica brushes should be highly abrasive. This usually means a decreased brush capacity and decreased lubricating values, although it is claimed for some brushes that proper abrasive effect is secured by hardening under enormous pressures, no abrasives being used.

7—For alternating current or slip rings the brushes should be as nearly self-lubricating as possible and should wear themselves rather than wear or cut the rings. These brushes may be of metal graphite composition or of a graphitic nature only. If of metal graphite they should not wear so as to form a continuous "fringe" or "wire edge" along the sides of the brushes at the rings, but should be of a mixture sufficiently granular to disintegrate and break away in small particles. The "fringe" or "wire edge" has been known to form and break away from the brush in full brush contact lengths, falling so as to bridge to adjacent rings and cause disastrous flash-overs.

After selection, the success or failure of a brush may be directly due to its application. This may be traceable to the following causes:—

1—The angle at which the brush is set. It is true that certain types of machines which are subject to frequent reversals, such as mill motors and street railway motors, may be said to automatically fix the brush position as radial, or practically radial. In the case of railway motors this is perhaps the universal practice. This does not mean, however, that if set at some angle, say 15 or 20 degrees, or even a greater angle, the average results might not be as good, if not better, than the radial setting. When machines are not subject to reversals, the proper angle will depend,—

(a)—Upon whether the rotation is against the toe or against the heel. (By "toe" is meant the point of the brush, or the side having the acute or small angle. The "heel" is, therefore, the side having the larger angle. This is independent of rotation.) If against the toe, the angle may be as great as 35 degrees or more, but above 35 degrees the toe becomes very sharp and mechanically weak. This point, therefore, must be guarded against. If against the heel, the angle may be from 12 degrees to 25 degrees. In instances where the brush touches more bars than required the sharp toes can be beveled off, thereby reducing the brush contact and the short-circuiting current under the brush, and at the same time increasing the mechanical strength of the brush. Whether running against toe or heel it is good practice to round off the sharp or knife edge of the toe. This reduces the possibility of the knife-like edges digging into the commutator in case the brushes jam or become tight in their holders, and at the same time protects against brush breakage.

(b)—Upon the friction coefficient of the brush. This factor is a decidedly variable one, being influenced not only by the inherent characteristics of the

*The Electric Journal.

brush, but also by the glazing of the contact face of the brush, the varying brush temperatures due to load and spring pressure, and the condition of the commutator—whether smooth or undercut, hot or cold, or in good, poor or bad mechanical condition. As a rule, bad mechanical conditions can be eliminated by properly seasoning the commutators and keeping them practically round, smooth and free from high mica. The other influences, however, are permanent, although they may be, in a measure, modified by finding a more suitable brush angle.

Brushholders

2—Brushholders vary widely in design. There is no universal holder. If the commutator or slip ring speed is low, a holder having a sluggish spring and slow action will give entirely satisfactory results; such a holder on a high-speed machine may fail miserably. High speeds require quickness of action on the part of the brush. This means a sensitive quick-acting spring and a holder designed to aid the spring. A high-speed holder may give excellent results on low-speed machines; but a low-speed holder is not likely to approach even fair results on high-speed machines. Brushholders should be designed to meet specified conditions, not merely designed to cheapen manufacture. Money is intelligently and economically invested when invested in well-designed, capable holders, but utterly wasted when "soaked" in flimsy substitutes. Much depends upon the type of brushholder. Certain fundamental requirements are often too indifferently regarded. Brushholders must be stable, and should be built on lines conforming closely to the lines of the brush as it will appear when in service.

The box, or part holding the brush, should be as nearly a full box as possible. To accomplish this, the shunt attachment (and brush-lifting clips when used) must be flush with the face of the brush, and the pressure spring so designed as to give maximum brush wear without necessitating too great slotting or cutting away of the holder on the sides. Whether the rotation is against the toe or against the heel, both the toe and heel sides of the holders should have approximately equal areas for the support of the brushes. It is obvious that the shorter the box, the greater will be the shifting movement of the brush on the commutator due to looseness in the holder; and the deeper the box, the less will be the shifting. From this it follows that the boxes should not be too short, nor should the brushes be too loose in the boxes.

It is an established fact that with even very slight play in the holder the changing brush friction due to load, temperatures, etc., will result in a changing relation between the brush and the commutator, and thereby cause changing and misleading brush drops from day to day. This accounts for the difficulty in verifying, on different days, brush drops, although the loads may be identical. The neutral does not change, but the relation of brush contact to commutator does change, and the brush drops vary accordingly.

Another explanation for the changes which take place in brush drops is that when brushes have been freshly "sandpapered" or "ground in" the surfaces have unglazed or soft faces, the brush drops being influenced by the porous condition of the faces, and the lubricating values of the particles liberated during the time the brush face is seating itself to the commutator. During this period the commutation, with certain kinds of graphitized brushes, may be much better than after the glaze or permanent surface forms on the brush. Drops taken during this time may not be the same as drops taken after the brush is "faced up" and may prove seriously misleading. Definite or reasonably permanent drop valves are, as a rule, to be had only after the brush faces have reached a fixed condition.

From the foregoing it it obvious that brushes should fit snugly, but not tightly, in the holders; also that there are certain relative dimensions which are preferable between the brushes and holders, and which must not be ignored if the best results are to be obtained. For instance, the side of the holder in the direction of rotation should not have less area than the lagging side. In fact, the side against which the brush presses should have preferably a greater area than the opposite side—certainly not less area. With a limited area to oppose the brush, movement of the brush in the holder, due to looseness, oscillation and imperfect relations between the brush and commutator, accentuates the change in the angle of contact, and results in poor commutation, as well as in mechanical and electrical damage to that part of the brush in contact with the holder.

SEWAGE PURIFICATION BY ELECTRICITY

By C. T.

THE uses of electrical energy are so vast that it is little wonder that attention is now being paid to its employment for sewage purification. A process has recently been invented by which crude sewage is passed through a trough, partially fitted with electrodes placed at right angles to the line of flow and connected in parallel with a current of low voltage. The system is based on the theory that sewage containing table salt and other electro is rapidly decomposed by the passage of the current and that caustic soda, nascent chlorine, hydrogen and oxygen are thus evolved. Part of the freed chloride combines with the soda, lime and iron thrown off by the electrodes, and hypochlorites are thus formed, which attack and break up the organic matter. Experimental plants on this system have been provided in several small communities with varying success. Another method has been tried in the borough of Queen, New York, and at the stockyards in Chicago. This system differs from the former by the provision of a paddle between each electrode, the rapid motion thus engendered keeping the sewage constantly agitated and the face of the electrode well secured. To obtain the requisite standard of purification, quantities of lime are added, and engineers are by no means in perfect agreement as to whether it is the lime or the electrolysis which performs the more efficient work of purification. The cost of working this system is unattractive, but it is interesting to learn that steps are being taken to harness electricity for the purpose of sewage disposal, as the subject is one of increasing importance and has not yet been perfectly solved.

Shawinigan Falls, Que.—The Shawinigan Water & Power Co. is preparing designs for a 5000 ft. clear conductor span for the transmission of electric energy over the St. Lawrence River at Three Rivers, Que., which will supplement the submarine cable transmission line already installed. Each of the steel towers on which the line will rest at the extreme ends of this long span will have a concrete base, set some little distance from the bank of the river. The towers will be 350 ft. high, so as to provide a clearance of 160 ft. in the centre of the span. The three conductors will be placed approximately 50 ft. apart. The transmission line will not be anchored to but merely supported by the towers and anchored to concrete blocks situated some distance to the rear of the towers.

Hydro May Expropriate Power.—Within a month or so the Ontario Hydro-Electric Commission will take steps to expropriate the power which is being exported by the Canadian Niagara Co. and the Electrical Development Co., if the developing companies refuse to supply the Hydro Commission with the amount of power they require. By this means 83,000 h.p. will be available to make up the shortage of power in the province. The Electrical Development Co. is exporting 50,000 of its horsepower, and the Canadian Niagara Co. is exporting 30,000 horsepower. The old Ontario Power Co., which the Hydro Commission purchased and took over a month ago, was exporting something like 40,000 horsepower. Now there is said to be 83,000 horsepower wanted by the Hydro Commission to make up the shortage of power, and this will have to be supplied by the two first companies.

Montreal, Que.—In a report signed by Messrs. H. E. Vautelet and A. St. Laurent, consulting enginers, the Board of Control is advised that the city proceed with the hydraulic development of the aqueduct along the lines suggested by them in Scheme 2 of their original report; they also recommend that the foundation of the power house be built as early as possible to insure the water supply of the city, while it is also suggested that the balance of the work be proceeded with along the lines recommended by them as circumstances will allow.

SKILLED MECHANICS A POST-WAR NECESSITY

THERE is a growing disposition to recognize that the peace-time essential of this or any other manufacturing country will be its muster of skilled mechanics. Shell-making has not, as is perhaps too generally believed, contributed materially to Canada's pre-war quota of the latter for, with the exception of a fair percentage increase, comparatively, in the ranks of her tool-makers and equipment designers, the abnormal activity of the past thirty months has done little more than demonstrate the possibility of rapidly training as attendants men who to all intents and purposes were in the rough so far as machine tool operating knowledge was concerned.

Shell manufacture was highly specialized, but in the nature of things was quite temporary in character. Urgency of production by the most direct means available was the keynote of the whole enterprise, as a consequence little opportunity was afforded for a widespread development in the training of expert mechanics, men who in the coming time would give our metal-working industries the degree of backbone and vigor which will undoubtedly be required if we are to procure and maintain a foothold in the world's markets. With the cessation of shell-making, attention is naturally being focussed on lines of product that will provide capacity activity for our now enlarged plant establishment, while giving at the same time assurance of there being retained in steady and continuous employment the skilled men now possessed, as well as providing opportunity for materially supplementing their numbers.

It should be borne in mind that, despite the war activities now so pronounced in the United States, and those no less in evidence in Great Britain and elsewhere, the keenest interest is being displayed in the matter of post-war trade preparedness, and that recognition as never before is being taken of the thoroughly trained and expert mechanic as the principal factor in the conditions with which we will be confronted. As an indication of how the subject is viewed in the Old Country, the following paragraphs culled from a recent editorial in our contemporary, *Engineering*, may not be without interest to our metal-working plant executives:

The deficient supply of skilled men is acutely realized and is exercising the minds of all who employ mechanics.

A man having the mentality, dexterity and character taken for granted or implied in the term skilled mechanic, or competent all-round craftsman, is prima facie a competent individual in a much wider manner than in a purely trade sense.

Natural aptitude, large mentality, resource, initiative, grit, character—all matters which make a man worthy of respect—are the inalienable possession of the man who becomes an expert mechanic.

Good mechanics were never plentiful, but present-day conditions have separated all men into two classes, those having skill and those without. Consequently, there has been a remarkable appreciation in value, the intrinsic worth of real skill has never been so realized as now. It is contended that, unless steps are taken to enable men to acquire real skill, invention will be paralyzed, improvement will be forfeited, and business some time or other will have to be rebuilt upon its old foundations.

How can we have mechanics unless we deliberately set out to produce them. Modern tendency is to commit industrial suicide. There are two outputs going on simultaneously from any business, products and men; the former earns profits, the latter serve a national as well as an industrial end. Plant can be extemporized more rapidly than skill, but if the result is to materially reduce the production of skilled craftsmen, then the industry must ultimately be penalized.

Academic training alone is no substitute, since it cannot produce the practical man of experience nor can it give manual dexterity of a high order. If the industry takes no steps to foster one of the most inherent of human desires—skill in the use of tools—it is going to decay and not to progress. Moreover, the nation which does not produce skilled craftsmen is going to forfeit industrial pre-eminence.

Association and Personal

Lieut. H. W. Morris, M. C., at one time chief electrical engineer of the Grand Trunk Railway, Montreal has been killed in action.

F. W. Darby, formerly advertising manager for Beattie Bros., Fergus, Ont., has been appointed to a similar position with the Waterous Engine Works, Brantford, Ont.

Alexander Wilson Crouch, vice-president and general manager of the Dearborn Chemical Co. of Canada, Toronto, sailed last Saturday on the S.S. Makura from Vancouver, on a year's trade expansion trip to the Orient, Australia, Korea and India. Mr. Crouch came to Toronto from Pittsburgh six years ago.

WATER GAUGE PACKING HINTS

SINCE the introduction of high pressure steam boilers, breakage of gauge glasses has caused much annoyance and given rise to numerous complaints. Many suggestions have been made of introducing substitutes, but the question arises, would the substitute be any better and may the gauge glasses now in use (if of good quality), not be sufficient for all that is required of them? We are of opinion that they are, provided always that the quality is good.

From a large number of experiments with Perth gauge glasses it has been found that these will stand a hydraulic pressure of five thousand lbs. per square inch without breaking. You may take one of them in your hand by one end and insert the other into a flame that will bring it to a red heat in about half a minute, without breaking.

Causes of Gauge Glass Breakage ..

Such being the case, the question naturally arises, why should a glass that will stand the variation of stress above five thousand lbs. hydraulic pressure, be broken with two or three hundred lbs. of steam pressure? To this it might be replied that in the one case the tests are done separately, while in the other the heat and pressure are combined. This looks like a formidable objection, but it is only so in appearance, as it can be proved that the glasses are broken neither by the pressure nor the heat, but by the expansion of the glass being interfered with.

Increased pressure of steam means increased heat, and the heat and pressure combined means an increase in the expansion of the glass. If the glass is packed too tightly, or in any way to interfere with its natural expansion, breakage is unavoidable, for it must break the moment it reaches the point of resistance.

With regard to the packing of gauge glasses, there are a number of points to be noticed; first, you must have a good gauge glass. There are glasses that will not stand two hundred lbs. pressure, pack them how you may. Again, glasses must not be too full for the size of the gland. More glasses are broken from this cause than would be credited, if the totals were known.

In the second place, the gauge cocks must be set perfectly true, otherwise the glass will have too little space for expansion on one side. Further, the packing must be suitable and of the very best quality. Rubber washers, even of first quality are not suitable of themselves, with steam at 200 lbs. or more, because they get softened to pulp in a very short time and are blown out. To prevent this, they should have a ply of asbestos twine or cord on each side.

The next point to be noticed is the screwing up of the glands. You should be able to move the glass with your finger and thumb after the screwing is finished. If you cannot do so the room for expansion is not sufficient and breakage will result. With the glass left easy there will be a little leakage when the steam is put on, but this will take up as soon as the glass and packing expands.

To insure perfect safety, however, it would be as well to slacken the nut almost to the leaking point again. One point to be particularly noticed is, that the glass breaks most frequently at the steam end of the gauge cock, that is because the steam is hotter than the water and causes more expansion. This should be kept in mind when screwing up the glands. If these directions are followed, a good gauge glass should stand perfectly well in the highest pressure boiler that has yet been made.

Gauge Glass Hints

As a proper packing of a gauge glass is so important to engineers and stokers, especially where high pressure boilers are used, the following hints may be found of service.

First, a good gauge glass must be used, which should not be too full for the size of the gland; second, a good rubber washer should be used; protected by a ply of asbestos twine on both sides; and third, the glass should be movable by the finger and thumb after the glands have been tightened up. The steam end of the glass should be left a shade slacker than the water end, and in every case the steam should be turned on gradually; and last, but not least, the whole operation should be carried out with intelligence.

This last instruction is quite as important as any of the others. Experiments have been carried out on a steam boiler with a working pressure of three hundred lbs. At first there were a great many breakages, but experience showed what kind of packing was required, etc., making it afterwards almost impossible to break one.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

North-West Association of Stationary Engineers, Edmonton, Alta.

Manitoba Association of Stationary Engineers, Winnipeg.

Canadian Association of Stationary Engineers, Hamilton, Ont.—Subordinate Lodges at Montreal, Toronto, Hamilton, Ottawa, Brantford, Guelph, Kitchener, Chatham, Ont.; St. John, N.B.; Owen Sound, London, Stratford, Belleville, Kingston, Sudbury, St. Thomas, North Bay, Port Arthur, Sarnia, and Windsor, Ont. The executive officers of the C.A.S.E. Grand Lodge are as follows:—

Past President—W. G. Forbes, Montreal, Que.
President—R. F. Gofton, Kitchener, Ont.
Vice-President—Wm. Cooke, Belleville, Ont.
Treasurer.—A. W. Heath, Hamilton, Ont.
Conductor—S. Balmfirth, Toronto, Ont.
Doorkeeper—George Moll, London, Ont.
Secretary.—John H. Hale, Hamilton, Ont.

Solder Data.—Suitable solders for any purpose can be made by judicious mixing of several constituents with lead and tin. For use in working at low temperatures, a low m.p. solder can be made by adding bismuth. A mixture of two parts of bismuth and one each of lead and tin melts at about 93 deg. Cent., while by the addition of mercury or alkaline metals, solders fluid at ordinary temperatures can be made. On the other hand, joints to withstand high temperatures can be made with brass, which requires the use of the blowpipe—hard soldering. In selecting a solder with respect to the temperature which the united metals can withstand, it should be borne in mind that the closer the melting points of solder and metals are together the better will be the joint.

The Operators' Point of View

WHAT HAPPENS TO TECHNICAL MAGAZINES

By A. F. Menzies

THAT a large amount of valuable information published in yours and other technical magazines is wasted goes without saying. A considerable reduction in this waste would take place if a convenient means of saving the information were available. If the magazines are preserved in their entirety, the amount of space required for their storage is considerable, and, after being consulted, unless carefully returned to their proper place, an extended search is required to find any given issue. It is rare also, that the title of an article is remembered, the index therefore, is not of much assistance.

Should the bound volume method be resorted to, the storage space required, although less, is still enough to make one think, especially if one has not finished ones wanderings. Further, a caluable part of the magazine, the advertising section, is lost. Clipping files of endless variety have been evolved; but for cheapness and convenience the following is hard to beat, specially for a beginning. After the file has grown large enough to warrant it and the owner thereof feels justified in making the investment, a metal filing case large enough to take the sheets without folding can be purchased.

A box of 250 common envelopes was obtained, the box was used as a filing case and the envelopes used to hold the clippings. It was found more convenient to remove the flap of the envelope. The index was arranged as shown in Fig. 1. By keeping the envelopes in alphabetical order no trouble is found in locating the one desired, and when located, the contents can be read at a glance. Care must be taken that the clippings are returned to the envelope and that the envelope itself is returned to its correct place.

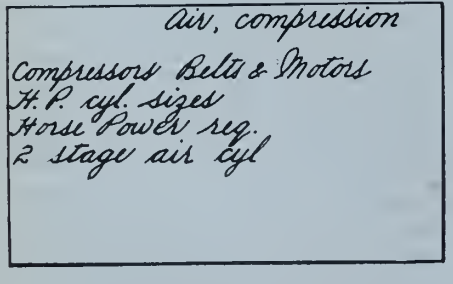

FIG. 1. INDEXED ENVELOPE.

To strengthen the box, strips of ⅜ in. tape were glued on as shown in Fig. 2. Small pieces of tape will also prevent the corners of the lid from cracking.

In reading over the magazines, the desired material can be marked and cut out at some future time, or simply cut out when it is decided that it is liable to be of use. It is as well to err on the side of too many clippings rather than to run the risk of enjoying the doubtful pleasure of kicking oneself for not keeping a certain article. The advertising section of the magazine should not be overlooked. Discounting the fact that the ad. writer is, so to speak, blowing his own horn, there is often as much meat to be found there as in the reading section.

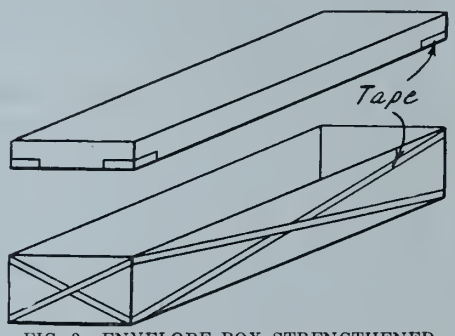

FIG. 2. ENVELOPE BOX STRENGTHENED WITH TAPE GLUED ON.

It sometimes happens that two desirable articles on widely different subjects are printed on the oppoite sides of the same sheet. It can, of course, only be filed under one head. To care for this a title of the other article with a very brief synopsis may be written out and noted thereon the heading under which the article will be found. This slip should then be filed in place of the article.

Such a method of keeping clippings is open to the objection that is applicable to any other thing that is worth while; in other words, to keep it up-to-date, a certain amount of persistence and patience is required.

GRAVITY vs. FORCE-FEED LUBRICATION

By R. Wood.

IN A recent issue of an American engineering journal, a correspondent recommends the old style gravity feed lubricator in preference to the oil pump. The writer presumes he refers to the automatic oil pumps which are stated to be wasteful.

Considerable experience with modern automatic force feed lubricators has shown them the exact opposite of wasteful and in my opinion they possess many points of superiority over the gravity lubricator. Some of these points are as follows:—

It it is desired to introduce a quantity of oil prior to starting a unit, all the operator has to do is to give the ratchet wheel a few turns by the handle placed on the wheel for this purpose.

The oil chamber can be filled and refilled while the unit to which it is attached is in operation and while the pump itself is in operation. If a small piece of sediment finds its way into the oil passage it can be forced out by giving the ratchet wheel a few quick turns.

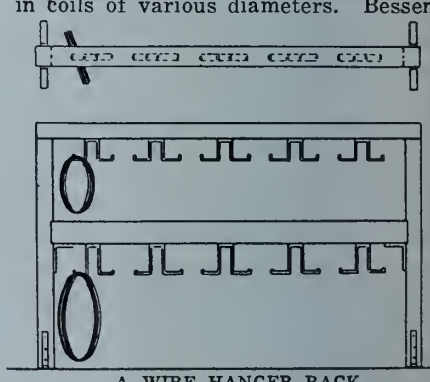
When the unit is started the pump starts feeding. When the unit stops the oil flow stops; there are no valves to open or close, no water to be drawn from the oil chamber.

The pump can be set to feed one drop a second or one drop a minute, that is, any speed of flow desired by the operator, and to regulate this flow all that is required is a turn or two on a regulating screw. This screw is the only thing the operator has to move. It requires about the same amount of work to install an automatic oil pump as it does to connect up a gravity automatic lubricator.

A WIRE HANGER RACK

By A. M. Y.

WIRE that is used for making springs and rivets, etc., usually comes wound in coils of various diameters. Bessemer spring wire coils being considerably larger of course than music wire. It is the usual practice to store these coils either on top of one another, or stand



A WIRE HANGER RACK.

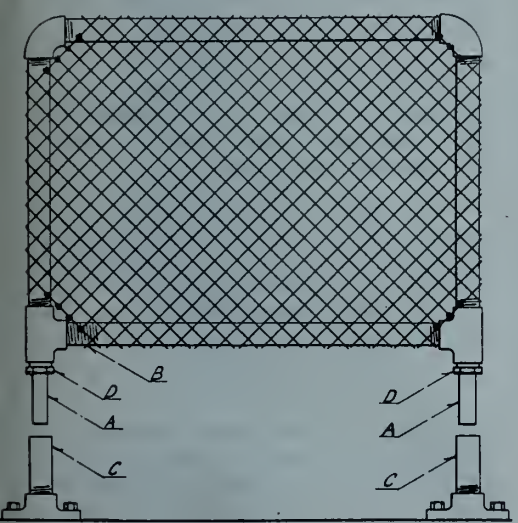
them endwise one against the other near a wall. In this manner they are hard to get at, besides, the ends become entangled with other coils and considerable difficulty is experienced in trying to separate them.

In the accompanying sketch is shown a wire hanger rack which is a very neat and convenient arrangement for hanging wire separately on books, whereby the coils are kept free from each other and are easily accessible when wanted. The rack is made from two by four lumber about 10 feet long, and 5 feet high. The lower rail is supported on the end by a forged bracket, and also four brackets support and hold the two uprights to the floor. The top rail is used for holding coils of small diameters, and the lower rail for larger diameters. The rack occupies very little space. The coils when placed on the hooks are turned slightly inward as shown in the top view of the sketch.

SIMPLE AND EFFECTIVE FLYWHEEL GUARD

J. E. N.

IN addition to the necessity of effective protection from the dangers contingent to machine shop and power house mechanisms, it is often advisable to make



SIMPLE AND EFFECTIVE FLYWHEEL GUARD

ample provision for the temporary removal of guards for repairs, cleaning up, etc. The guard shown herewith was installed to protect workmen from the flywheel on an engine, but same could be applied in any other dangerous location. As shown, the frame consists of 1½-inch pipe connected with standard fittings. Owing to the continuous construction of the frame, the last joint shown at B was made with an extra long thread so as to avoid left-hand fittings. In the outer end of each tee was placed a 1½-inch to 1¼-inch bushing D, into which was secured a short length of 1¼-inch pipe A, previously turned to a diameter that would slip into the short piece of 1½-inch pipe, screwed into the supporting wall or floor flange. The frame is covered by 1¼-inch mesh wire screen, a feature that prevents the hand or arm from being thrust through in case of a fall. A frame of this description can be readily lifted from its position for necessary repairs, the supports remaining fixed to the wall or floor.

KEROSENE AS MOTOR FUEL

By C. T.

IT is evident that the day is not far distant when kerosene will be as commonly used in engines of motor cars and tractors as gasoline is at present. The search for another substitute than that of some petroleum product has been an utter failure. It began with the high price of gasoline some four years ago, and has been continued ever since. Various suggestions have been made and numerous times it has been reported that a substitute had been found which would furnish cars with a cheap fuel and drive gasoline out of business. It will be remembered that English inventors were sure a few years ago that they could substitute benzol for the American article, but they never carried the demonstration beyond a few cars, because the article was too scarce and too costly. An American inventor drove cars round the race track in Indianapolis for several weeks with a fluid that could be produced at the small cost of a few cents a gallon. It was a failure in the end. Last year a Long Island chemist had a green fluid, which, added to water produced at any pump or creek, promised relief from high-priced gasoline. He drove cars with it, or with something, and even deceived several noted inventors. The green fluid suddenly disappeared from public prints, and the auto owners waited for some other inspired article.

Meanwhile inventors turned their attention to the use of the cheaper kerosene as a substitute. Engines have since then been run on kerosenes with the introduction of small amounts of water in the cylinders. This has been practically demonstrated in a factory in Allegany County, New York, and two years ago a car crossed the Continent with no other motive power than kerosene. A few months ago a car was taken from Warren, Pa., to New York over heavy roads and through bad weather, and with no other fluid than was obtained from the kerosene stores along the route. The facts prove the possibility of the use of the heavier article for autocars and other engines.

It is now recognized that only slight changes are needed in the carburetter to make the use of kerosene as common as that of gasoline. This is also proved by the fact that much of the gasoline now used is the same specific gravity as the lighter grades of kerosene of the past years. The gravity of gasoline has been gradually lowered to meet the demand for more motive power for automobiles, aeroplanes and motor boats, and the engines built at present handle it freely. Necessity has brought this about, and with the awakened interest in the heavier article the demand will be met.

DOES A PISTON STOP AT REVERSAL?

By R. W. Miller.

HERE is an interesting question about which a controversy has arisen in connection with recent litigation. Put into its simplest form, the question is—does the piston of a steam engine stop when its direction is reversed, this is assuming that there is no lost motion in the parts?

Strange as it may seem. engineers, attorneys and examiners in the Patent Office disagree on the question. I maintain that it does not stop, but that the motion is continuous, and I would be interested if some reader of the POWER HOUSE can prove that I am wrong. To stop means to produce a state of rest—in other words, then, if the piston stops it must rest—then, how long does it rest?

The curve of a piston's motion, provided the connecting rod were of infinite length, would be truly harmonic. According to one authority, "a harmonic motion may be defined as the motion executed by the foot of a perpendicular let fall on the diameter of a circle from a point moving with uniform velocity along the circumference."

It is unnecessary to reproduce here a harmonic curve, because it is one with which we are all familiar. We know that no portion of this curve contains any part of a straight line. Now if there were a rest at each end of the stroke there would be two flat portions at each extreme of the travel parallel with the base line. One flatly contradicts the other.

One man argued that there was a point where there would be no motion; what becomes of this argument when we know that a point has no magnitude? Finally, if the piston stopped even for an infinitesimally small fraction of a second would not the flywheel to which it is connected stop also?

To controvert the theory that the flywheel stops, we find in the definition quoted that the point executing the harmonic motion must move with uniform velocity. How can the flywheel stop twice in one revolution, and yet have any point in its circumference move with uniform velocity?—the motion of the piston is just as continuous as the flywheel.

STEEL CHIMNEY TROUBLES

By T. J.

CHIMNEYS built up of steel plates require protection both inside and outside, if they are to have reasonably long life and perform their work properly. The outside of a chimney is exposed to the action of sun, wind and rain, and the approved method of protecting it from rust is to give it a coat of good paint, which should be renewed whenever and wherever it shows signs of peeling off and exposing the metal to the influence of the elements. On the inside the chimney is exposed to the action of the gaseous products of combustion, which may have a temperature of several hundred degrees. Any form of paint would, therefore, be quite useless. Besides it

must be remembered that the gases which flow up the chimney are derived from the combustion of fuels containing carbon, hydrogen, and sulphur, and, therefore, contain carbon dioxide. steam and sulphur dioxide. The steam in the chimney gases will condense if cooling takes place to any great extent, and the moisture will combine with the dioxides of carbon and sulphur to form carbonic acid and sulphurous acid. Both of these acids are corrosive in their action on iron, and they are particularly active in the presence of heat. Therefore, the inside of the chimney needs to be well protected.

The usual method of protecting the interior of a steel chimney is to line it with brick, which is laid up against the wall of the chimney. It is advisable to fill the interstices between the lining with a grout made of cement, as this will not only give support to the brickwork, but will at the same time prevent the corrosive acids from reaching the shell. Such a lining should extend to the top of the chimney to be effective. If it is carried up only half-way or even to two-thirds of the full height of the chimney the corrosion is localized at the part of the structure that it is most difficult to reach. The formation of moisture, due to condensation of vapor in the flue gases, will occur in the upper part of the chimney rather than in the lower, because the gases grow colder as they ascend, due to radiation from the shell of the chimney. It is, therefore, very advisable to carry the lining all the way up to the top.

It will be found upon observing steel chimneys that are in service that the signs of discoloration and corrosion on the outside are largely confined to the upper half of the structure. The rings or sections composing the chimney are put together in such a way that each overlaps on the outside of the ring below it, so that the edges of the circumferential seams face downward outside. This construction prevents rain and snow from collecting on the edges of the plates outside. On the inside, however, the edges face upwards, and if moisture is formed it will lodge on these edges, find its way through the joint and run down outside, streaking and discoloring the chimney. A continuous lining from the top to the bottom will lessen the radiation loss, reduce and perhaps eliminate condensation and in any case eliminate the moisture from the edge of the plates.

TEMPORARY REPAIRS TO GAS ENGINE GOVERNOR

By J. E. McCormack.

IN a gasoline engine governor of the type shown in section in Fig. 1, the arm A, broke at the hinge pin. Weights DD were connected by springs, as indicated in Fig. 2. Before the engine stopped, one of these springs became badly stretched, but was put back as well as possible later. For a temporary quick repair, a piece of wood was cut as in K. Fig. 3, the side projection being shaped to fit down against the balance wheel hub and into the space between the spokes and was then attached to the yoke E, Fig. 1, by means of a suitably

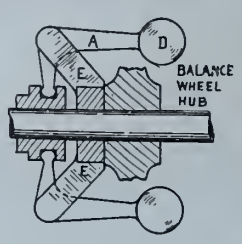


FIG. 1.

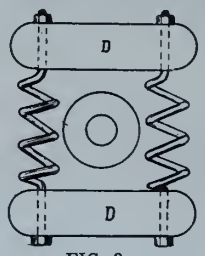

FIG. 2.

bent carriage bolt shown in Fig. 4. Smaller bolts were dropped into the springs FF (one into each spring), and a washer slipped between two coils of each spring and above the ends of the aforementioned small bolts. These bolts were then passed through the washers and through the wooden piece K, and washers and nuts put on these. The washers in the springs were large enough to hold the springs to K, yet small enough that the bolt heads did not pull through them.

After being planned, the repair did not require much time for its accomplishment, and the engine was again started. According to the speed indicator, it ran about eight per cent. slower than normal when first started, which was not considered bad, considering the stretched condition of the springs. They were, however, tightened a little more and operations continued; although the engine did not run quite so steadily as formerly, it was considered much better than shutting down to await new parts. The one weight acting alone against K. instead of against a duplicate of itself was much like one pulling on a rope tied to a post as compared with his pulling against another man on the some rope. The two pulling equally merely balance each other, the strain would be equal to

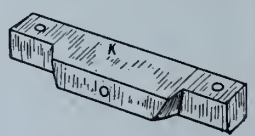

FIG. 3.

FIG. 4.

the pull of one and the same as though the other end were fastened to something solid.

I might also add that with this engine a cord was passed from the ignition switch up through a pulley and across to where the operator of the driven machinery could easily reach it and thus cut out the ignition and so stop the engine whenever he wished. Also the priming bottle used was decorated with a large diamond shaped red label to prevent anyone mistaking the contents for kerosene or other liquid.

Charles, aged five, having been told that baby sister had just arrived from heaven, marched into the room and said: "Now, Miss Baby, tell us all about heaven 'fore you forget it."

Screenings

Proud mother of young Corporal Jones: "You've heard about my boy, of course, Mrs. Evans?"

Mrs. Evans: "No. What is it?"

Mrs. Jones: "Why, just think—they have made a cockerel of him!"

"And how do you find school, Harold?"

Rather difficult, sir. The teachers are inconsistent. In English composition we are told to be original. In arithmetic we are all expected to get the same answer."—Louisville Courier-Journal.

A nervous man at the opera sat behind a pair of those persons who explain the plot until his endurance was exhausted. Then he leaned forward and said:

"Excuse me, will you speak a little louder? Sometimes the music prevents my hearing what you say."

Teddy had been invited out to tea. He wanted to have the afternoon off from school, but his mother would not hear of it. As his bedtime was 7 o'clock he had rather a short visit, and as he was leaving his hostess said cordially:

"I'm so sorry you've been able to stay such a little while, dear."

Teddy remembered his mother's injunctions to be polite on all occasions, and answered, sweetly: "Oh, it's quite long enough, thank you."

"Dear Clara," wrote the young man, "pardon me, but I'm getting so forgetful. I proposed to you last night, but really forgot whether you said yes or no."

"Dear Will," she replied by note, "so glad to hear from you. I know I said 'no' to some one last night, but I had forgotten just who it was."

A certain learned Queen's counsel was arguing a commercial case before a learned judge. In doing so, he had occasion to speak repeatedly of an "eccentric," and the judge at length asked him what an eccentric was. The magistrate said he was familiar with the term as applied to individuals, but not to things. The Queen's counsel at once complied. "An eccentric," he said, "is a circular disk whose centre is not in the middle."

"I tell you, gentlemen," said the great explorer to the crowd in the hotel smoking room, who were listening breathlessly, "you can't imagine what things are like out in the Arctic regions!"

"Oh, I don't know!" said one. "Even if we haven't seen it, we can imagine what it feels like!"

"I doubt it. It's impossible until you've seen it; until you've stood there, a small, insignificant atom, surrounded by vast stretches of white—"

"Yes, I know. I've been like that."

"Really? Where was it, may I ask?"

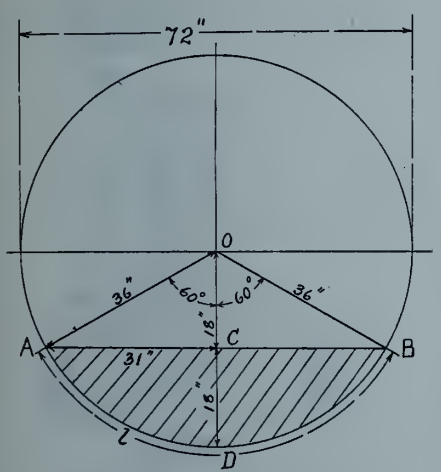
"First time I appeared in public in a dress shirt!"

Operators' Instruction Course

EDUCATION PAPER.—III.

HOW many gallons of water are there in a cylindrical tank 72 in. in diameter by 18 ft. long, which is filled to a depth of 18 in.?

The problem is solved by finding the number of cu. in. or cu. ft. in a body of water 18 ft. long, having a cross section represented by a segment of a circle whose radius is 36 in. and height of segment 18 in. The accompanying sketch shows how the area of the segment is found. The shaded portion ACBD is the segment corresponding to the body of water in the tank, and in



order to find its area it is necessary to find the area of the sector AOBD and deduct the area of triangle AOB. Area of sector AOBD = length of arc ADB × half the radius OD. To find length of arc ADB calculate angle AOB in degrees thus: AO and OB are radii = 36 in.; OC = 18 in.; and sine of angle AOC = 18 ÷ 36 = ½ so that angle AOC = 60 deg. Angle AOB will be twice this = 120 deg.

The circumference of 72 in. dia. = 226 approximately therefore as angle AOB is 120 deg. or one-third of the circle, arc ADB will be one-third of the circumference 226 = 75.3. 75.3 × 18 = 1355 area of sector AOBD. Area of triangle AOB = half the base × height, and half the base = AC = $\sqrt{(36^2-18^2)}$ = 31. Therefore 31 × 18 = 558, area of triangle AOB. Deducting 558 from 1355 leaves 797 area of segment ACBD, in sq. inches. 18 ft. = 216 in. which, multiplied by 797 = 172152 cu. in. The number of cu. in. in an imperial gallon is 277.274 and dividing this into 172152 = 657 1/3 gallons approximately.

(Note). The foregoing shows one method of finding the answer mathematically where a considerable degree of accuracy is necessary. Owing to manufacturing problems it is not possible to get a tank which might agree accurately with calculated results but in any case it would be more accurate than any rule of thumb methods which operate only within small ranges of variation. The question of contents at different depths in horizontal cylindrical tanks is of wide spread interest and in an early issue in hope to publish a chart which by means of simple arithmetic will give accurate figures for any proportion of contents.

* * * *

What horse-power is required to raise 600 cu. ft. of water per min., lifting it 20 ft. and then forcing it to 140 ft. in height, allowing 25 per cent. for friction?

Horse-power equals foot pounds per minute divided by 33,000. The foot pounds here are equal to the weight of water, multiplied by total height in feet through which it is moved: a cu. ft. of water weighs 62.32 lbs., which multiplied by 600 = 37,392 lbs. Multiplying this by the total height in feet, 160 we have 5,982,720 ÷ 33,000 = 181.29. The 25 per cent. allowance increases this by 45.32 making the total horse-power required 226.57.

* * * *

What relation is the decimal point and a whole number to each other? Give demonstrations of same.

When placed after a whole number, the decimal point indicates that whatever figures follow after, represent tenths, hundredths etc. respectively, and in this case does not affect the figures in front of it. When moved to the left past the figures in a whole number, it reduces the value of each to one-tenth. Thus—3.5 is three and five-tenths, 74.26 is seventy-four and two-tenths and six hundredths: .35, pronounced "decimal three five" or "point three five" is three tenths and five hundredths: 7.426 and .7426 are respectively one-tenth and one hundreth of 74.26.

* * * *

Add 12.6798, .0346, 1.32, .0035, 5.3621.

Arrange the numbers as for ordinary addition putting each decimal point immediately below each other and add vertically commencing with the extreme right hand figures only, thus:—1, 5, 6, and 8 = 20; carrying two we have 2, 3, 4 and 9 plus 2 = 20; again, 6, 2, 3 and 7 plus 2 = 20; again, 3, 3, and 6 plus 2 = 14. The 4 is placed under the first column of decimal figures, one is carried over to the first column of whole numbers and the sum finished. Answer 19.4.

* * * *

Subtract 6.6794 from 12.7896, and 145.280 from 176.7.

Proceed as in ordinary subtraction placing decimal points below each other, and where there are no decimal figures to correspond, fill up with ciphers.

Thus:
```
  12.7896
   6.6794
  ------
   6.1102
```

And
```
 176.700
 145.280
 -------
  31.42
```

* * * *

Divide 33 by .055; 55 by .015; 426 by .1278.

Proceed as in ordinary long division and if there is a point in the divisor move it to the right hand end of the number, making it a whole number. At the same time, if there is also a decimal point in the dividend, move it a corresponding number of spaces to the right and insert the decimal point in the quotient as it is reached thus:

(1) .055) 33 (becomes.

```
55) 33000 (600
    330
    ---
      00
```

(2) .015) 55 (becomes

```
15) 55000 (3666.6
    45
    --
    100
     90
    ---
     100
      90
     ---
      100
       90
      ---
       10.0
```

(3) .1278) 426 (becomes

1278) 4260000 (3333.3

Steam Power Plant Auxiliaries

PRESSURE REDUCING VALVES—I.

THE ever increasing complexity of modern manufacturing processes renders it necessary in many factories to use steam at widely different pressures — heating, cooking, dyeing, boiling and drying, etc., are some of the numerous applications with which readers are familiar. Frequent use is also made of reducing valves on board ship, where the high pressure necessary for the main engines is reduced to pressure suited to the various auxiliaries throughout the ship. In both cases, the necessity exists for a device which will automatically control the flow of steam from the

FIG. 1.—EXTERIOR VIEW OF "J.M.T." REDUCING VALVE.

the main engines is reduced to pressures system, operating to close down as the low pressure builds up when not in use, and opening up to pass more steam when additional demands are made on the low pressure system.

In view of the damage which might ensue from an unexpected or uncontrolled rise of pressure in many plants, the necessity of using reliable apparatus will be admitted, and the several types of valves on the market to-day are the result of many years of attention and experiment by makers and users over a wide range of conditions. Usually the initial or high pressure is subject to more or less radiation through [illegible] wide ranges, and, as frequently occurs, the low pressure side is also liable to variation at the same time. This latter condition alone has been one of the most difficult conditions influencing reducing valve design and it has been the aim of all modern designs to meet this condition with the simplest possible mechanism.

"J. M. T." Reducing Valve

An exterior view of this valve is shown in Fig. 1, and a sectional view in Fig. 2, the manner in which the reduced pressure is maintained at the desired degree being understood by reference to the numbered parts thereon. The main valve 19, is held on its seat by spring 18, the upper end of which rests against the fixed socket or bushing 7. This bushing forms a guide for auxiliary valve 8, which seats on the bottom end of bushing and controls the admission of high pressure steam to the port 15, which in turn is connected by a small passage (not shown in cut) to the underside of piston 11 below main valve 19. The upper end of auxiliary valve 8 makes contact with diaphragm 6, the underside of the diaphragm being subject to steam pressure from the reduced side through the passage shown at the left. This pressure is opposed by the action o spring 4 on its upperside, suitable adjustment being obtained by handwheel as shown.

When there is no pressure on either side, the main valve is closed and the auxiliary valve is open. When high pressure steam enters the inlet, it immediately passes through auxiliary valve and ports to the underside of piston 11, which, because of its larger area, raises main valve 19 off its seat and allows steam to pass to the outlet. The pressure on the reduced side now increases to the point at which regulating spring 4 is set, and when slightly in excess of it, raises diaphragm 6 and allows auxiliary valve 7 to close slightly, the upward movement of this valve being obtained from spring 14. This movement reduces the flow of steam to the piston 11, which is a loose fit so as to allow a free leakage to the outlet. When the amount of steam passing the auxiliary valve becomes less than that leaking past the piston, the piston will be pressed down by the pressure of spring 18 on top of main valve, and the flow of high pressure steam reduced accordingly.

This action takes place in greater or less degree, according to the amount of low pressure steam required, the main valve assuming a position which furnishes just sufficient steam to maintain the desired pressure on the low side. Should the outlet be closed the pressure forces the diaphragm up far enough to allow auxiliary valve to close completely, thus removing all supporting pressure from piston 11, and allowing main valve to close tight till such time as the outlet pressure falls and allows diaphragm to open auxiliary valve again.

This valve is made in a full range of sizes and in various styles by the James Morrison Brass Mfg. Co., Toronto, and is furnished for ranges of reduction from 5 to 50 lbs., 50 lbs. to 140 lbs, and 140 to 300 lbs., these being obtained by substituting springs of suitable strength.

Fulton Reducing Valve

This valve is illustrated in Figs 3 and 4, and dispenses with the use of pilot or auxiliary valves. Referring to sec-

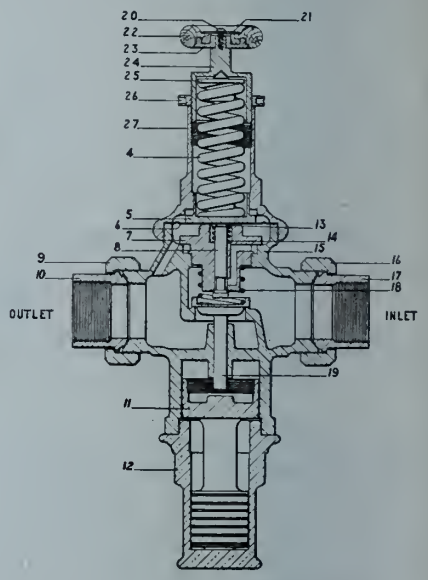


FIG. 2.—SECTIONAL VIEW OF "J.M.T." REDUCING VALVE SHOWING OPERATION OF MAIN AND AUXILIARY VALVES

tional view Fig. 4, it will be seen that a double beat valve is employed. The valve spindle extends upward through a packing gland to a yoke operated by lever and counterweight which tend to keep the valve open. The upper end of the yoke extends into a diaphragm chamber as shown, supporting a diaphragm whose upper side is connected by ⅜-in. pipe to the outlet main, and is thus exposed to the reduced pressure.

As the pressure on the outlet builds up to the desired point, the diaphragm is subjected to increased pressure, which finally overcomes the counterweight and commences to close the valve and reduce the flow of steam to the required amount. An increase of the outlet pressure about that adjusted for will close

the valve entirely and a drop will allow it to open more.

The Chaplin-Fulton Mfg. Co., Pittsburgh, make this valve in from 3-in. to

FIG. 3.—EXTERIOR VIEW OF FULTON REDUCING VALVE SHOWING COUNTERWEIGHT, LEVER, AND CONNECTION TO OUTLET MAIN

12-in. sizes, while below 3-in. the lever and weight are replaced by a long coil spring, which, with the diaphragm, is arranged below the valve body, the outlet pressure being conveyed to the upper side of the diaphragm directly through the body casting. The lever on the large sizes is balanced on a knife-edge fulcrum and supports the valve stem by means of a toggle connection which reduces friction and insures quick response to the slightest change of load.

Ohio Brass Pressure Regulating Valve

All of the several types of this valve operate on the same principle, employing a single seated main valve, and dispensing with weights, dashpots or pistons. It is operated by controlling the relation of pressures on the two sides of a metallic diaphragm, which is attached to the stem of the main valve. The control of these pressures is accomplished by a small controlling valve, which in turn is operated by the service pressure acting on one side of a small metallic controlling diaphragm against a controlling spring on the other side of the diaphragm. The operating and controlling diaphragms are both metallic and their movement is restricted within their elastic limit to avoid any danger of permanent distortion, the difference in pressure between the upper and lower sides of the operating diaphragm is never greater than about 15 lbs., and ordinarily is maintained at about 10 lbs.

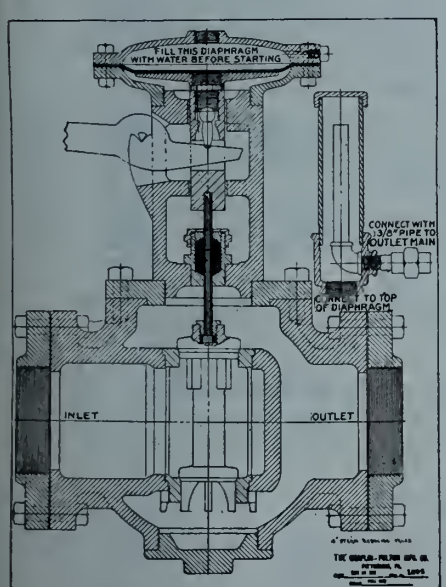

FIG. 4. SECTION OF FULTON REDUCING VALVE SHOWING DIAPHRAGM AND KNIFE EDGE CONNECTION TO COUNTERWEIGHT LEVER.

The type F valve illustrated in Fig. 5. is adapted to pressure from 0 to 15 lbs., 5 to 20 lbs, and 25 to 100 lbs., in sizes from ½-in. to 2-in. When high pressure steam enters the valve body at A, it passes up between the stem of the main valve 13, and guide nut 15 to the chamber E below operating diaphragm 19, and at the same time obtains access to the upper side D of the diaphragm through the internal ports C in the stem of the main valve. Thence it passes by way of passage F and external pipe 23 to controlling valve 25, which is held open by the upward pressure of adjusting spring 30, and thus allows the steam from the upper space D to pass right through to the low pressure side B of the main valve.

The difference in pressure between the upper and lower sides of the operating diaphragm forces the diaphragm upward compressing spring 14, and opening main valve to allow passage of steam to outlet. As the low pressure builds up, it acts against adjusting spring 30, through controlling diaphragm 27, so that controlling valve 25 closes when the reduced pressure is reached.

The closing of this valve prevents any further flow of steam through passage from the upper side of the operating diaphragm, so that the pressures on each side of it equalize and allow spring 14 to close the main valve. Adjusting spring 30 allows the controlling valve to close at any desired pressure with its range of adjustment; in actual operation, of course, the controlling valve does not close completely, but alters its position according to the flow of steam through the outlet—when the latter increases, the drop of pressure allows diaphragm 27 to rise so that the pressure in space D above the large diaphragm is reduced and the main valve allowed to open up more due to the greater difference of pressure between the two sides. The reverse action takes place when the outlet flow is reduced and the reduced pressure rises, the main valve floating and adjusting its opening continuously to the demands for steam on the reduced pressure side.

This valve is made by the Ohio Brass Co., Mansfield, O., who embody the same principle in type G valve, sizes 2½ in. to 4 in., which has a balanced main valve and other changes demanded by the increased capacity.

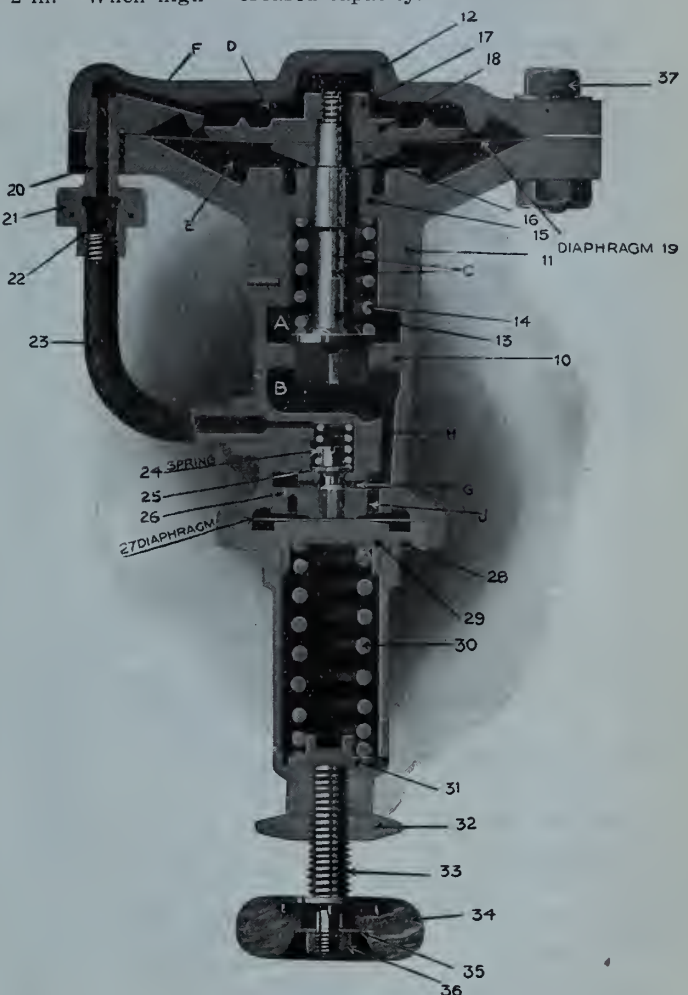

FIG. 5. SECTIONAL VIEW OF "OHIO" BRASS VALVE SHOWING LOCATION OF PARTS.

A NOVEL method of repairing worn armature shafts on the commutator ends of its motors is being employed by the Elmira Water, Light and Railroad Company. Steel tubing, which has an outside diameter equal to that of an unworn armature shaft, plus a very thin skin cut, is employed, and the worn shaft is turned down so that the tubing can be put over it with a shrink fit. To ensure a tight fit between the sleeve and the shaft a circular groove is cut in the end of the shaft along the joint between the steel sleeve and the shaft. This groove is then welded full of metal and the shrink fit and the weld are said to give the required strength.

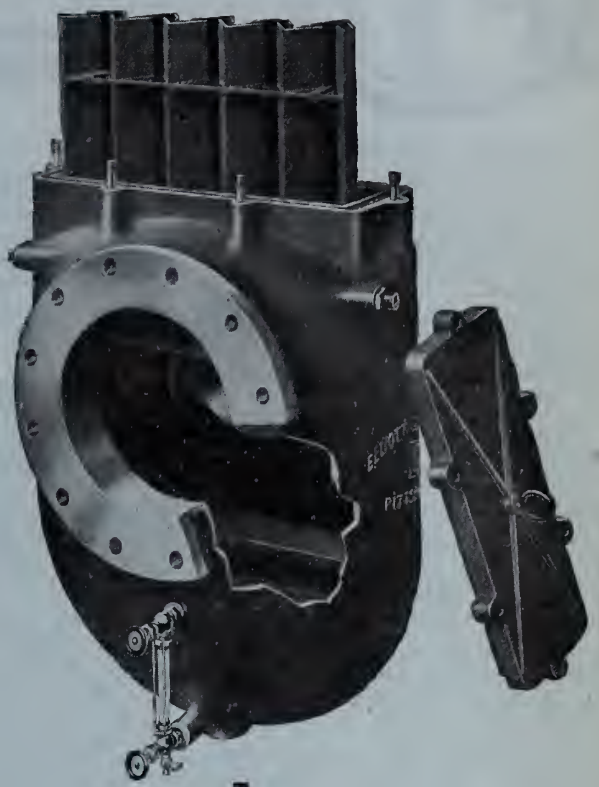
ELLIOTT
Oil Separators

Have baffle plates that can be removed from the Separator and cleaned when they become gummed with oil.

The double row of V-Shaped baffle plates in Elliott Oil Separators, Type "P," collect the particles of oil and conduct them out of the path of the steam.



Type "P"
Oil Separator
showing how the baffles may be removed for cleaning.

In some types of Oil Separators a flat or corrugated baffle plate is interposed in the path of the steam—the idea being that the particles of oil which are traveling at an enormous velocity will hit it head-on and in some manner or other be so broken up that they will cease to exist. The impact or collision may serve to break up the particles of oil into still smaller particles, but little is accomplished toward getting the oil out of the steam as the particles of oil will rebound back where they can be picked up again and carried on with the steam.

A similar action will be observed if you direct a stream of water under pressure against a wall at right angles to the flow of water. The impact breaks up the stream into hundreds of small drops, which rebound back in all directions. If the stream of water were directed against the wall at an angle, practically all of the water would be deflected in the same direction.

This is the principle of the V-shaped baffle plates in the Type "P" Oil Separators. The first row merely directs the stream at the proper angle against the second row of baffles which in turn throws the particles of oil back into the recess angles of the first row so that the oil is completely out of the path of the steam.

The baffle plates are kept moistened with jets of water from a spray pipe (see spray pipe connection at side of accompanying cut.) With the baffle plates in a moist condition the particles of oil readily form into globules or large drops and run down into the reservoir.

The first step in learning more of the Elliott Oil Separators is sending for Bulletin "E." It is yours on request.

Projects and Developments

Kingsville, Ont.—The Town Council contemplate installing a pumping plant.

Port Dover, Ont.—The Town Council will proceed with the installation of a waterworks system now that the by-law has carried.

Portage la Prairie, Man.—The Town Council will install a 100 h.p. boiler with mechanical stoker in its electric station at a cost of $5,000.

Oshawa, Ont.—A contract has been awarded to the Chapman Valve Mfg. Co., Toronto, for the valves required for the filtration plant being built here.

Drummondville, Que.—The Southern Canada Power Co. have awarded a contract for a 400-h.p. single vertical turbine to the S. Morgan Smith Co.

Dorval, Que.—The Norwood Engineering Co., Cowansville, Que., have been awarded the contract for filtration plant to be installed here at a cost of $35,300.

New Toronto, Ont.—James, Loudon, & Hertzberg, the town's consulting engineers, have recommended the purchase of a small motor-driven centrifugal pump.

Toronto, Ont.—The directors of the Canadian National Exhibition may decide to build an auxiliary electrical power plant of their own in the near future.

Pointe Claire, Que.—The Town Council have awarded a contract to the Turbine Equipment Co., Toronto, for 2-motor driven De Laval single stage pumps, for the municipal filtration plant.

The Turbine Equipment Co., Toronto, have received an order for a 125 h.p. motor driven De Laval 2 stage pump, from the city of Belleville, Ont. This is the fourth De Laval unit purchased by this city.

Oshawa, Ont. — The Turbine Equipment Co., Toronto, have secured a contract from the Town of Oshawa, for 2-De Laval single stage, motor driven centrifugal pumps, for the new filtration plant which is being constructed here.

Yorkton, Sask.—The Siemens Co. of Canada, Ltd., Montreal, have been awarded a contract for a generator to be direct connected to a Diesel engine. The generator will be 400 k.v.a., 60-cycle, 3-phase, 220 volt. A direct connected exciter is also included in the contract.

The Yamachiche Electric Light Co. has been incorporated at Ottawa with a capital of $100,000, to operate an electric light and power plant at Three Rivers, Que. The incorporators are: J. E. Marier, J. E. Cadotte and E. Cherette, all of Montreal.

Dundas, Ont.—The Canadian Engineering & Contracting Co. of Hamilton has been awarded the contract for repairing the waterworks reservoir. The tender was $2,808, the lowest received. The work will be commenced in two weeks' time.

Brantford, Ont.—The City Council have awarded a contract to the Turbine Equipment Co., Toronto, for 2-De Laval single stage, motor driven pumps, for the booster pumping station. This is the second order within the last three years for De Laval pumps for this city.

The Turbine Equipment Co., Toronto, have recently secured the following contracts. One motor driven multistage De Laval pump for operating against 400 feet head, for the mining corporation of Canada, Cobalt, Ont. A similar unit for operating against 450 feet head for the Casey-Cobalt Silver Mining Co., New Liskeard, Ont. Two De Laval steam turbine driven centrifugal pumps for the new Union Station, Toronto.

Nelson, B.C.—A new light and power corporation has been organized known as the Northport Power and Light Co., to supply light and power to this district. Its principal place of business will be Northport, and branch offices will be maintained both in the United States and Canada. One of the directors is Lorne A. Campbell, of the West Kootenay Light and Power Co.

St. John's, Nfld.—R. H. Reid, vice-president of the Labrador Pulp and Paper Co., is credited with saying that the undertaking would mean the development of one of the most important water powers in the country, the falls on the Hamilton River are second to those of Nagara. The bonds of the company will not be placed on the market, and the increased capitalization will all be met by private subscription.

Toronto, Ont.—Tenders will be received, addressed to the Chairman, Board of Control, City Hall, Toronto, up to October 2, for the construction and delivery of stop valves, valve operating, pump and special castings, for main pumping station. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall.

Toronto, Ont.—Hon. F. G. Macdiarmid, Minister of Public Works, announced the other day that a beginning had been made on construction of the necessary plant at Lakes Nipissing and Nepigon for the handling of fish caught in those waters under the new fisheries plan of the province.

CATALOGUES

The Canadian S K F Ball Bearing Co., Toronto, have for distribution among their friends a handy pocket rule in English and metric measurements. The rule is 6¼ inches long and will be gladly mailed to anyone interested in ball bearings.

The S. K. F. Ball Bearing Co., Hartford, Conn., have issued a folder containing photographs and statements from a number of prominent machine tool manufacturers giving their opinion concerning the use of S K F ball bearings on the machines which they make.

Firebox Boilers. — Catalogue No. 62 issued by the Dominion Radiator Co., Toronto, illustrates and describes the Safford-Kewanee firebox boilers for steam and water heating. The catalogue also contains specifications pricelists and sectional views of boiler settings.

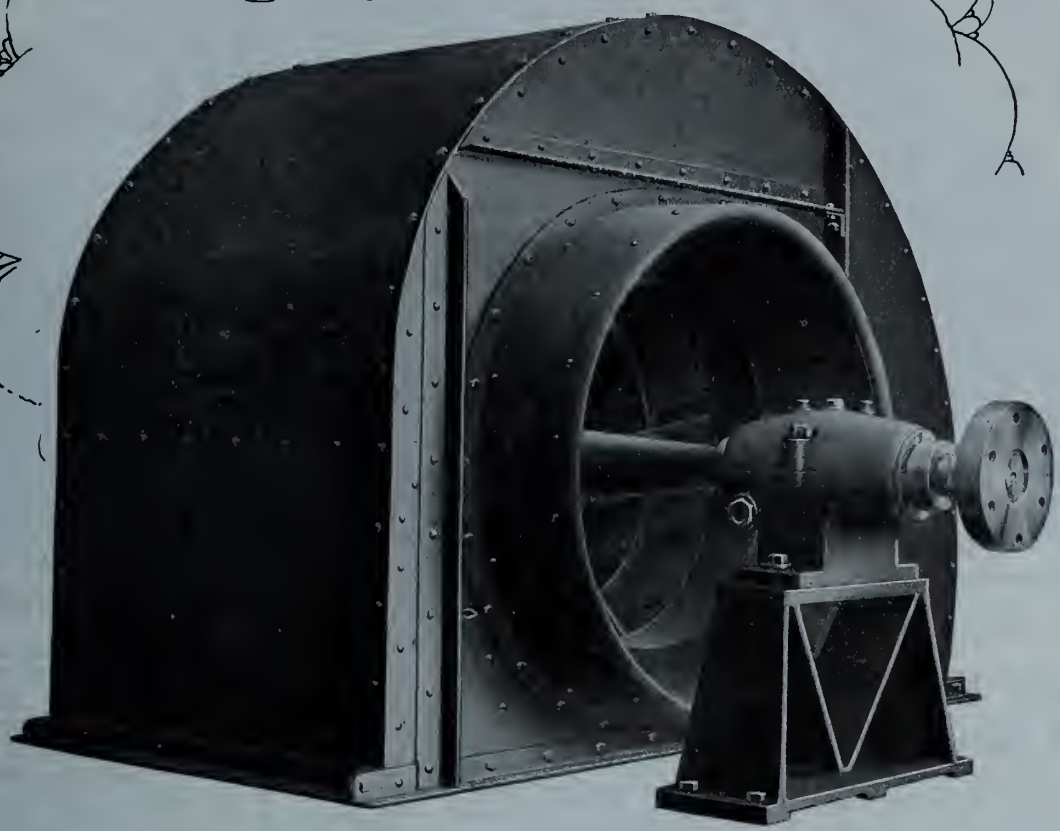
"Mor-Lite" Plant.—Canadian Fairbanks Morse Co., Montreal and Toronto, have issued an attractive booklet illustrating their Mor-Lite self-starting, self-stopping and self-running electric light generating plants for private use. Complete specifications of the plant are given, and its compactness combined with convenience for country homes are the chief features.

Darling Bros., Ltd., of Montreal, Que., manufacturers of steam appliances, have recently issued a special catalogue for distribution abroad. This booklet is 6 by 9 in. in size, containing 24 pages, and printed in French on high-quality calendered stock. Many of the lines manufactured and handled by this firm are profusely illustrated and described, with the data and prices arranged and compiled to meet the requirements of foreign countries familiar with the French language.

Engine Room Supplies is the title of a booklet recently issued by the Quaker City Rubber Co., Philadelphia, Pa. This booklet is exceptionally complete and comprehensive, and will serve as a useful guide to the engineer in selecting packings, hose and other necessary engine room requirements. The principal lines described include Daniels', P. P. P., rod packing, Ebonite sheet packing, gaskets and steam hose, "Crown" and "Quaker City" packings. The booklet is pocket size and contains 63 pages with index.

A Chain of Evidence is the title of publication No. 14, dealing with large power drives manufactured by the Morse Chain Co., Ithaca, N.Y. The bulletin illustrates and describes a num-

Announcing the Design 4 Turbovane Fan



The Sturtevant, Design 4, Turbovane Fan is a new development for high speed forced draft work.
It has an exceeding high efficiency, not only at full load but over the entire useful range. The efficiency curve is practically flat between ¾ load and 1¼ load, which gives high operating efficiency over a wide range of conditions—either at peak load, full load, or when operating below normal.
Engineers familiar with the very varying loads in power plants and with the changing demands upon the fan, will realize the immense importance of a fan with this characteristic.
Our engineers will explain more on request.

ber of important Morse chain installations in various plants showing the wide field of application for transmitting large powers. The bulletin also deals with the construction of the Morse chain and the advantages obtained by its use for large power drives. Copies of this publication may be obtained from the Canadian agents Jones & Glassco, Montreal.

Steam Pumps.—A 90 page catalogue No. 12, issued by the Smart-Turner Machine Co., Hamilton, Ont., is devoted to steam pumps and covers only the designs and sizes ordinarily called for. The catalogue, however, deals with a varied line and includes pumps for practically all purposes. Each type is illustrated, while tables are included, giving sizes and capacities, etc. The concluding pages contain useful hydraulic tables, directions for installing and operating Smart-Turner pumps, and also directions for setting steam slide valves of the duplex pumps.

BOOK REVIEW.

The Economical Purchase and Use of Bituminous Coal for Heating Homes.—The University of Illinois has issued a circular dealing with the economical operation of small house heating plants and the saving in coal that can be effected. The University of Illinois has discussed, in the circular referred to, the more important factors involved in the installation of a satisfactory house heating system, and has set forth the most economical methods of firing soft coal and operating a house heating plant. The properties of fuels, and the proccesses attending their combustion are discussed in a fashion which is intended to help the average householder to understand his problem and to secure the economics of intelligent operation. Copies of this circular may be had by addressing the Engineering Experiment Station, Urbana, Illinois. The price is ten cents.

Progress in Water Works Pumps.—Waterworks pumping plants have recently undergone a rapid and radical evolution. The tremendously heavy and expensive, although efficient, triple-expansion pumping engine has given place to the more compact, simple and less costly steam-turbine-driven centrifugal pump. The efficiency of the latter has risen steadily with the experience of its builders and with improvements in auxiliary equipment, until duties under standard steam conditions exceeding 150,000,000 ft. lb. per 1,000 lb. of steam are now obtained. The De Laval Steam Turbine Co., of Trenton, N.J., builder of the largest pumps of this type, has just issued, under the title "Progress in Water Works Pumps," a 48-page booklet discussing the general economic and engineering conditions affecting the design and installation of such pumps. Installations in 15 of the principal cities of the States and Canada are described, including 34 units aggregating 999,000,000 gals. per day capacity.

NON-CORROSIVE

NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.

FRICTION LOSS

You may have attributed your friction losses to everything else but your oil. Yet nine times out of ten that is the source. An oil that is purely oil, perfect in its lubricating qualities, and free from all imperfections, should eliminate all friction; make a noticeable reduction in your coal bill; lessen oiling and firing costs; promote speed, and prove the source of greater efficiency to the whole system. If your oil is not performing these duties—consult us. Kellogg Non-Corrosive Cylinder Oil is being used by a great many of Canada's leading manufacturers for the above points. Consult us.

The Choice of the Fittest

There is no city where the inspection of efficiency in steam appliances is more rigid than in the City of Toronto. And there is no institution in the City of Toronto more particular than the new General Hospital in the matter of superior equipment.

were selected in preference to all others in this famous institution only after a most thorough investigation of their exceptional merit.

are of reliable construction.

Seat rings are independent rings of bronze, or any special metal that best suits the requirement. They are held firmly in position, without distortion, by retaining rings of bronze, which are screwed into the body of the valve. The retaining rings can be removed easily with a wrench made for the purpose, thus allowing new seat rings to be placed in the valve without removing the valve from the line.

GRATON & KNIGHT

Standardized Series

LEATHER BELTING

Tanned by us for belting use

GRATON & KNIGHT

Common Sense in the Standardization of Belting

You have standardized your signature.

You buy standardized tools, standard printing paper and a hundred other standardized things, instead of having them made to order. It is safer for you — easier and more economical.

Why don't you standardize your belting?

Consider what standardization has done for your own product; for other products you use.

Translate these advantages into terms of belting.

Analyze belt installations. You find the requirements of power transmission fall into a small number of sharply defined classes — about a dozen if you define them scientifically.

Standardized Belting offers you a standard belt that is exactly suited to each one of these classes. You adopt the one that is fitted to the needs of your own work. That is standardization—just plain common sense applied to power transmission.

There are Graton & Knight Heart, GraKnight, GraKnight Dynamo, Spartan, Neptune and other Standard Brands—all standardized on the basis of work to be done and conditions to be met.

Standardize your belts. Consult our representatives. Submit your power transmission problems to our mechanical laboratory—get *expert* advice.

Write for description of Graton & Knight Standardized Series of Leather Belts, with full information about Standardization as applied to Belting.

Oppenheim

John Bayne Maclean

COL. MACLEAN contributes another chapter on the war situation as he knows it, in his forceful, smashing style. These articles by Colonel Maclean are truly startling by reason of their revelations.

Germany's Secret Work in Canada

GERMANY is plotting in Canada and the United States right now. If you are curious to know just what she is doing, learn from Miss Agnes C. Laut's article in the October MACLEAN'S, "The Plot Behind the Pacifists."

THE biggest single feature ever secured by MACLEAN'S MAGAZINE is a serial story by E. Phillips Oppenheim, British author and a great writer of romantic stories.

The serial beginning in MACLEAN'S for October is "The Pawns Count," a story of the present war, dealing with the work of the secret service agents of the various belligerent countries. You can depend on its being a strong, thrilling story, told by a master of his craft.

BELAND
Prisoner of War

THE HON. LOUIS BELAND, a prisoner in Belgium since the beginning of the war, gives the story of his captivity, chiefly in the form of letters to Sir Wilfrid Laurier, in whose last cabinet he held a portfolio.

The story is intimate, vivid, gripping, wholly unusual, and appears in the October MACLEAN'S.

Beating the Customs

AN article full of actual occurrences of how the public attempts to "beat" the Customs, and of how the Customs authorities beat the public. This absorbingly interesting narrative is by J. D. Ronald who, as a Customs officer, came into close touch with offenders and offences. A semi-detective article, this true story makes great reading.

Stringer, Fraser, Leacock and Hendryx

THE work of these masters of the short and long story appears in the October MACLEAN'S. Stringer's story is "The Redeemer of Waste Lands"; W. A. Fraser writes a love story, "For Catherine's Sake"; Leacock has a humorous sketch; and Hendryx continues his captivating story of the Canadian Northwest, "The Gun Brand."

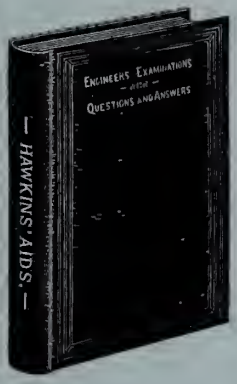
Hawkins' New Catechism of Electricity

It contains 550 pages with 300 illustrations of electrical appliances; it is bound in heavy red leather, with full gold edges and is a most attractive handbook for electricians and engineers. One-third of the book is devoted to the explanation and illustrations of the dynamo, with particular directions relating to its care and management—$2.10 post paid.



Engineers' Examinations

By N. Hawkins, M.E.

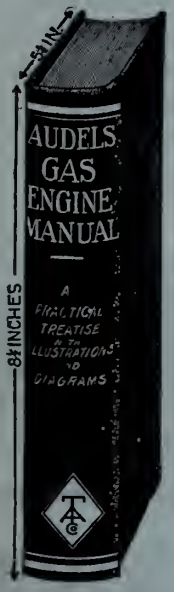
It presents in a condensed form the most approved practice in the care and management of steam boilers, engines, pumps, electrical and refrigerating machines, with examples of how to work the problems relating to the safety valve, strength of boilers and horse power of the steam engine and steam boiler.—$2.10 post paid.

Steam Turbines

By Leland.

A reference work ou the development, advantages and disadvantages of the steam turbine; the design, selection, operation and maintenance of steam turbine plants and turbo-generators. 135 pages. Illustrated.—$1.00.

Audel's Gas Engine Manual



A practical treatise relating to the theory and management of gas, gasoline and oil engines, including chapters on producer gas plants, marine motors and automobile engines.—$2.00.

Hydraulic Engineering

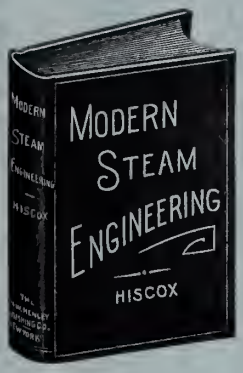
By G. D. Hiscox.

This comprehensive book of Hydraulics written by an experienced engineer, is a practical treatise on the properties, power and resources of water for all purposes, including the measurement of streams, the flow of water in pipes or conduits; the horse-power of falling water; turbine and impact water wheels; wave motors, etc. All who are interested in Water Works Development should have a copy. 320 pages, 305 illustrations. Price $4.15 post paid.

Compressed Air

By L. I. Wightman, E.E.

A reference work on the production, transmission and application of compressed air; the selection, operation and maintenance of compressed air machinery; and the design of air power plants. Illustrated.—$1.10.



Modern Steam Engineering in Theory and Practice

By Hiscox.

This book has been specialiy prepared for the use of the modern steam engineer, the technical students, and all who desire the latest and most reliable information on steam and steam boilers, the machinery of power. tne steam turbine, electric power and lighting plants, etc. 450 pages. 400 detailed engravings.—$3.15 post paid.

Boiler Construction

By Kleinhans.

The only book showing how locomotive boilers are built in modern shops. Shows all types of boilers used; gives details of construction; practicai facts, such as line of riveting punches and dies, work done per day, aliowance for bending and flanging sheets and other data that means dollars to any railroad man. 421 pages, 324 illustrations, six folding plates.—$3.00.

Compressed Air, Its Production, Uses and Application. *By G. D. Hiscox, M.E.*

Comprising the physical properties of air from a vacuum to its liquid state, its thermodynamics, compression, transmission and uses as a motive power in the operation of stationary and portable machinery, in mining, air tools, air lifts, pumping of water, acids aud oils and the numerous applicances in which compressed air is a most convenient and economical transmitter of power.—Price $5.15 post paid.

Boiler Accessories

By Walter S. Leland, S.B.

Assistant Professor of Navai Architecture, Mass. Institute of Technology, American Society Navai Architects and Marine Engineers. 144 pp., 80 illus. Cloth binding. A treatise giving complete descriptions of the various accessories of the boiler room and engine room essential to economicai operation, such as evaporators, pumps, feed-water heaters, injectors, mechanical stokers, etc., with practical instruction in their use.—Price $1.10 post paid.

Forgetting

One of the things we all do well is to forget.

Names that were household words yesterday are gone to-day.

Because people knew your Name and your Line a year ago it is no sign they do to-day. They forget easily.

Keep yourself in the public mind by advertising. It is just as important to make old friends remember as it is to win new friends. Advertising does both.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

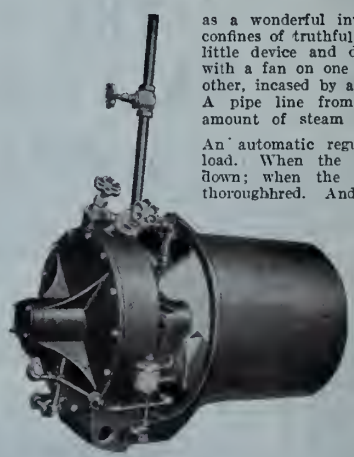
"Doing Our Bit"

We believe we are "doing our bit" in demonstrating to manufacturers how they can effectively cut down the cost of steam production, better their combustion and increase the capacities of their boilers. In offering the

Coe Turbine Blower



as a wonderful invention, we are well within the confines of truthful advertising. It is such a simple little device and does such a big work! A shaft with a fan on one end and a steam turbine on the other, incased by a shell is about all there is to it. A pipe line from the leader supplies the small amount of steam required.

An automatic regulator adjusts the speed to the load. When the load is light, the blower slows down; when the peak comes it responds like a thoroughbred. And how it does drive the air into the fire! Clinker doesn't get a chance to form.

The gases of combustion which ordinarily pass up the chimney are held back by the draft controller, thoroughly mixed with the air and burned. Nothing gets away that is worth keeping.

Space limits prevent a complete description of the Coe Turbine Blower. Write for it and receive our special demonstration proposition. You should have it. We solicit your inquiry.

DART UNIONS give you absolute protection against leaks. They cost you nothing for upkeep.

They cost you nothing for replacements.

They are easily connected.

They are without equal.

HERE'S THE SECRET of DART UNION Success

BRONZE TO BRONZE AT THE JOINT

When the Bronze faces of the Dart Union Pipe Couplings are drawn together, you have a joint that defies the stress of time, pressure, corrosion, vibration and expansion.

Dart Union construction portrays the most advanced idea in pipe coupling of this progressive age.

Practically everlasting—bronze faces do not deteriorate, and heavy iron parts will not stretch or pull apart.

It matters not if pipes are out of alignment in making a Dart Union Coupling—ball-shaped seat allows for an easily-made and perfectly tight connection in all cases.

Join the enthusiastic throng of Dart Union users. Order from your jobber.

LUNKENHEIMER
Pop Safety Valves

For all types of steam boilers.

Encased or exposed spring. Material combinations to suit all service conditions.

Bronze Pop Safety Valve. Encased Spring.

Full relieving capacity is a virtue in Lunkenheimer Pop Safety Valves. Their peculiar construction incorporating an improved "pop" mechanism, together with the large areas through the body, make this a certainty.

They are economical because of their durability,—which means low maintenance cost. The high-grade materials used vary for the different parts, being formulated especially for the duty each part performs. The workmanship is Lunkenheimer "Quality"—that high order which characterizes all Lunkenheimer Products.

Each valve is put through a rigid test under live steam before leaving the factory. It is set and the "pop" carefully adjusted to meet the service conditions for which the valve is intended.

Lock-key attachment is provided to guard against their being tampered with and provision is made for inserting inspector's seal.

Your local dealer can furnish them; if not, write us. Write for Booklet No. 502-DC which illustrates the complete line.

Insurance

A STEAM joint blown out means loss — loss of production, loss of money.

And many times it means injury to employees — together with costly damage suits.

A cheap sheet packing of the ordinary type can easily cause any or all of these.

You should buy a dependable quality of sheet packing.

Goodyearite has won its supremacy in the industrial world on its merits.

Made up of the longest fibres of the best rock asbestos obtainable and manufactured by a special process, it has more asbestos and less filler than any sheet on the market.

Goodyearite is safe for high pressure and superheat steam, strong and dilute solutions of acids, alkalies, general industrial chemicals, gas and gasoline.

Tested under 750° of heat, Goodyear gaskets were in usable condition when removed.

Goodyearite is stocked by mill supply and hardware dealers, and by Goodyear branches. It comes in sheets 36″ x 36″ and in thickness of 1/32″, 1/16″, 3/32″ and 1/8″. Because its weight per square yard is light, Goodyearite is economical as well as safe.

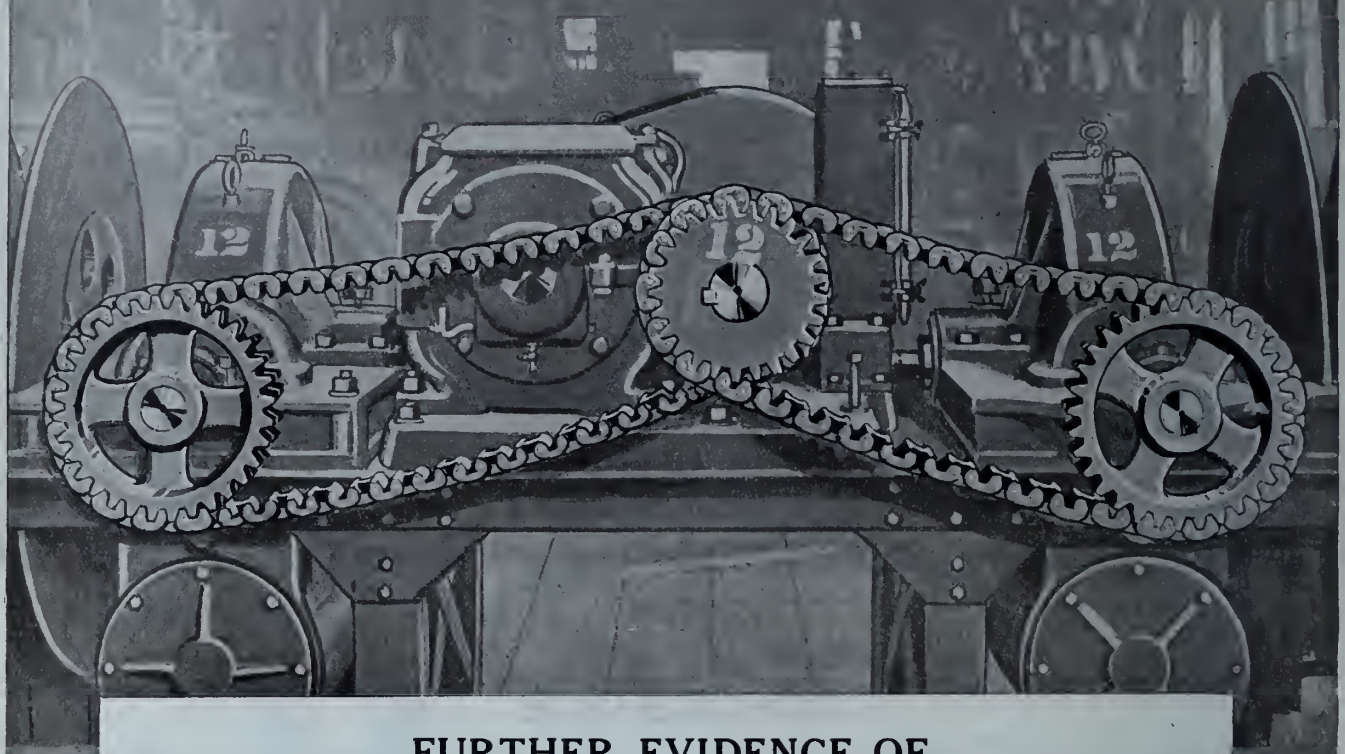
MORSE SILENT CHAINS OPERATE PANAMA CANAL EMERGENCY GATES



FURTHER EVIDENCE OF

Morse Dependability

THE UNITED STATES GOVERNMENT, before selecting the form of POWER TRANSMISSION which should operate the Emergency Gates of the Panama Canal Locks, made a comparative investigation of all the large manufacturers of Silent Chains, putting their products through searching tests of STRENGTH and ADAPTABILITY.

MORSE SILENT CHAINS showed a much higher tensile strength than any other make, and were selected as the chains which could be depended upon in emergencies. Accordingly, the Otis Elevator Co., which installed the 36 Control Units was instructed to operate them through MORSE SILENT CHAINS. One of the units is pictured above.

Write us for still further evidence of the Government's confidence in "MORSE." Government tests are worth investigating.

"Good Morning, Jim."

"Good morning, Mr. Hawley."

The new Superintendent had stopped in the engine room, where Jim, the Engineer, was getting everything ready for a flying start. The company had a big Government contract, and was running twenty-four hours a day, six days a week, three shifts and five engines, four of which were running.

"What are you doing with No. 5, Jim?" asked Mr. Hawley. "Got some belt trouble?"

"No sir. While she's shut down I've had George paint the back of that new belt."

"Paint it?"

"Yes sir, with CLING-SURFACE. You see, all belts get pretty dry, and it used to bother me a lot until I got this CLING-SURFACE. Well, the company advises painting the back of a good clean belt with CLING-SURFACE, so it will soak it up quicker and prevent cracking, and I gave it a trial. That's the new belt—all the others were painted about a year ago."

"How do they work?"

"Fine! There's the belt on No. 1. I had that painted last year, when Mr. Hodges was Superintendent, and put the CLING-SURFACE on just warm enough to use. You'd be surprised how quick the stuff got into the leather, and since then it's just as clean and pliable as a kid glove."

"Do they slip?"

"Not a bit. George puts a little CLING-SURFACE on the belt face with a stick about once or twice a week—just as fast as they will take it up, and the belts always pick up the load and hold it. And I haven't had to take-up any of them since this treatment was started a year ago."

* * *

It is a patriotic duty to conserve your present equipment. Instead of buying new belts, treat your present drives with CLING-SURFACE, and make them last longer and work better for you.

Prove it at our expense. Order a 25 or 50-pound can on trial—60 days, and with these results guaranteed before you pay.

Remember, use CLING-SURFACE and you won't need belt dressings.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penaltiea set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways. W. C. McGHIE, Chairman of Board.

W. A. RIDDELL M. A., PH. D., Superintendent, Trades & Labour Branch.

McDANIEL IMPROVED STEAM TRAP

FOR HIGH OR LOW PRESSURE.

Steam can't blow through. They have large discharge valves and cannot be flooded from sudden flushes of water.

MAY WE SEND ONE FOR TRIAL?

Reducing Valves, Pump Governors, Relief Valves, Exhaust Pipe Heads, Ejectors and Steam Separators.

Canadian Association OF Stationary Engineers

"The objects and purposes of the Association shall be to promote by all lawful means the efficient operation of steam and electric power plants, and for the said purposes:

(a) To serve as a school of instruction for its members;

(b) To hold meetings for discussing theoretical and practical matters pertaining to its calling;

(c) To examine stationary engineers and firemen as to their proficiency, and to grant graded certificates of ability to its members, and to be a medium through which steam and electric users may be supplied with good and reliable engineers, and to grant relief to its members in cases of sickness and distress."

By joining one of the subordinate associations of the C.A.S.E. you will be greatly benefited. For full particulars write

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID.
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

D. M. MEDCALF,
Chief Inspector of Steam Boilers.

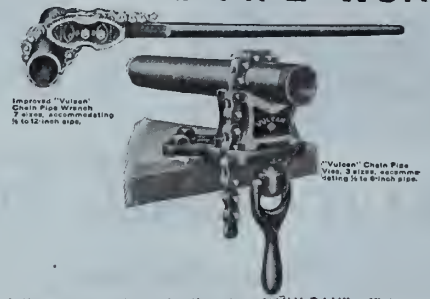
VULCAN-IZE PIPE WORK



Improved "Vulcan" Chain Pipe Wrench 7 sizes, accommodating ⅛ to 12-inch pipe.

"Vulcan" Chain Pipe Vise, 3 sizes, accommodating ⅛ to 6-inch pipe.

Only the penny wise begrudge the price of "VULCAN" sufficiency. Experienced buyers will take nothing else.

Double life, proof-tested chains and knowledge of security are worth all they cost—and more.

TO THE MAN WHO KNOWS THE "VULCAN"

J. H. WILLIAMS & CO.
THE WRENCH PEOPLE
78 HIGHLANDS STREET BROOKLYN, N.Y. CITY

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

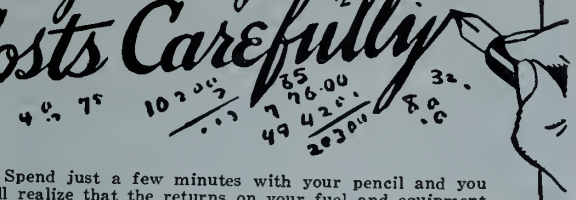
Figure your Costs Carefully



Spend just a few minutes with your pencil and you will realize that the returns on your fuel and equipment investment can be surprisingly increased with a MOREHEAD "Back to the Boiler" SYSTEM.

Every heat unit in your steam represents so much coal—so much cold cash. The MOREHEAD SYSTEM enables you to get full use of every one of these heat units. The

Morehead
Back to Boiler
SYSTEM

takes every ounce of condensed moisture from your steam lines and returns it to the boiler—without waste—automatically. The operation is 90% cheaper than a pump can do it—and the condensation is 100 to 150° hotter.

If you want the very best method of handling condensation — interest yourself in the MOREHEAD SYSTEM.

Belting Advice

Tell us your belting troubles.

We will be glad to help you solve them no matter what make of belting you use. Ask us to help you chase belting troubles out of your plant. **Our service s free.**

TRADE MARK LANCO BALATA BELTING

Lanco Balata is as nearly stretchless as it is possible to have a good belt and is really waterproof.

SCANDINAVIA FEDERAL ENGINEERING & SUPPLIES LIMITED TORONTO BELTING

The original solid woven cotton belt. Edges treated to resist shifters. Can be used in most places that leather is used.

Have you our belting book? Sent free on request.

Federal Engineering Co., Limited
172 John St., Toronto

Paid For Itself in Thirty Days

The chances are that if a device does not prove its worth in thirty days there is little chance that it ever will. But think of this

"Detroit" Systems for Handling Condensation

have records of paying for themselves in thirty days.

Not only will a "Detroit" System pay for itself in a short time, but will continue to save hundreds of dollars a year right in your boiler room by saving fuel.

In your boiler room, as in many others, there is perhaps no adequate provision made to return the condensation.

Better let us send you "Watch Your Condensation."

Mechanical Regulation of Boiler Feed Water

By the use of the "S-C" method you are assured of a continuous feed at all times load is on boiler. The graduation in rate of feeding is entirely dependent upon the load and fire conditions. The Regulator will carry a constant level on steady load—higher level on light load and lower level on peak loads. Variation in water level is entirely dependent on inclined position of generator which is adjustable while operating under full load.

Bulletin No. 80 explains all.

Generator or Actuating end of Regulator.

Regulating Valve Placed at Any Point, Any Position.

Water in Boiler

What Protection Have You?

When your water runs low at some moment when you are busy; when the water runs too high when you are in some other part of the building; what is your warning signal? An Anderson Water Column will whistle at either of these two extremities.
It is built with the inherent qualities that characterize all Anderson goods. An inquiry will receive our prompt attention.

The
V. D. Anderson Co.
1935 West 96th St.
Cleveland - Ohio.

Davis Pressure Regulators Save Steam

Don't Waste Steam

You carry high boiler pressure for emergencies and peak loads, but are you sure this reserve is not slipping away? You know only too well the cost of coal —conserve it by keeping your steam pressure under full control with

DAVIS PRESSURE REGULATORS

Put these automatic valves to work wherever you can use less than boiler pressure. The cost is trifling and the saving big. Forty years on the market is enough to prove they are built right. Send for catalog. It will show you a way to cut costs.

G. M. DAVIS REGULATOR CO.
434 Milwaukee Avenue
Chicago - - - Illinois

Vigilant Regulator

Built on New and Logical Lines and is a

BIG SUCCESS

The VIGILANT Regulator has NO FLOATS—therein lies the secret of its success. For floats, notwithstanding all claims to the contrary, under heavy pressure sooner or later waterlog, collapse, and leak; water seems to penetrate the pores of the metal. With floats eliminated the seat of all trouble is eliminated, too. The VIGILANT has no floats, no diaphragms, no complicated system of levers and small valves, no concealed or obscure steam passages. It is logically designed to meet all requirements on a new and successful principle.

Secure full details.

Lighten the Labor-Load

All labor works most efficiently and economically under favorable conditions.

Canadian plants are being pushed to the utmost — increased production is the cry to-day—speeding up labor is difficult—

It is much easier to induce labor to work where conditions are right. All production operations are best conducted under natural conditions, but working two or three shifts a day, it is impossible to operate under the natural conditions of daylight. Therefore, the matter of giving labor a light most nearly approximating daylight during the hours of darkness, is of prime importance.

To the engineer—the lighting expert — and the plant owner, whose interests are identical in this matter—these facts are self-evident.

How to secure daylight in darkness is the problem.

THE LACO NITRO LAMP

"The Light That Gives More Light"

SOLVES THIS PROBLEM

We offer in the Laco Nitro Lamp a tungsten filament in a nitrogen gas filled bulb. This lamp represents the highest development of the tungsten lamp. The tungsten filament in the nitrogen filled bulb gives a clearer, whiter light and greater candle power per watt than any other type lamp.

Inquire from your nearest dealer. Stocks available at Montreal, Toronto, Winnipeg and Vancouver warehouses.

Plibrico — Endorsed by some of the leading Engineers as the Greatest Furnace Lining of Recent Times

PLIBRICO—makes a solid one-piece lining without joints. Absolutely gas and air-tight. Saves its cost in fuel in a month or two—you will have a steady fire with less effort and less coal by using it.

PLIBRICO—is mixed ready for use, requires only half the time to install and does not require skilled labor. Any laborer who is at all familiar with the building line can use it. DOES NOT BREAK, CRACK OR SHELL OFF LIKE ORDINARY BRICK.

Can be used for front door arches, side walls, bridge walls, combustion chamber and rear arches. A highly refractory, plastic, one-piece furnace lining for boilers, baffles, Dutch oven construction, cupolas, retorts, enamelling furnaces, gas and oil-fired furnaces, and wherever a high-grade fire brick is required. Sets quickly—after a few hours with a low fire to draw off the moisture, you may fire up as usual. No special forms required.

Ideal for temporary repairs. Better order a barrel and have it ready for an emergency.

PLIBRICO BOND—A high temperature cement for repairs

"PLIBRICO BOND" is a product which gives a perfect bond between fire-brick, and does not allow the fire to burn out the joints, as is the case where fire-clay is used. Prevents furnace walls from cracking and crumbling.

It's the most practical and logical high temperature mortar you can use. It's the ever-ready repair cement that you should have in case of emergency.

Canadian Sales Agents **Beveridge Paper Company, Ltd., Montreal, P.Q.**

Advertising makes for a better product—

Not only does advertising create a good impression regarding the product advertised but it **makes for a better product.** There are added responsibility and written-printed claims to substantiate.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

INGLIS

The Standard of Merit

Inglis Turbine Engines

are used in power plants of Canada from the Atlantic to the Pacific. They set the standard of merit and efficiency, combining *durability, reliability* and *economy.*

Oil ring bearings, hydraulic balance and water-cooled thrust bearings are features of their ideal construction.

Impellers and passages are highly finished, all working elements being carefully balanced against vibration.

Illustration No. 1 shows our Multi-stage split case Turbine Pump for medium and high pressures. Direct connected to electric motor.

Illustration No. 2 shows Double Suction Pump for circulating low or medium heads. Direct connected to steam turbine.

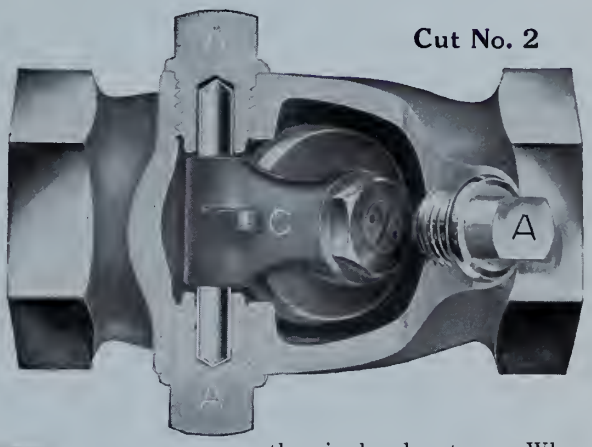
REGRINDING SWING-CHECK VALVES

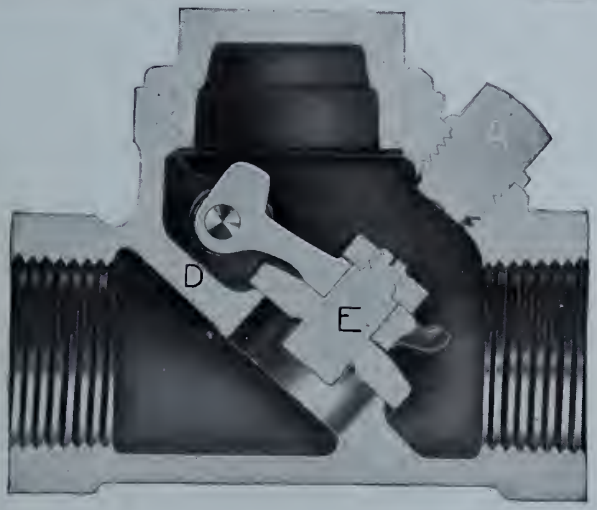
The Check Superior

Cut No. 1

Cut No. 2



Cut No. 3



Cut No. 1

Shows an external view of the Penberthy Swing Check Valve and illustrates location of top and side plugs, which features are described in following description. The above illustration also gives a good idea of the symmetrical design of this superior check.

Cut No. 2

Shows a sectional top view. The Penberthy Swing Check is what is termed a double plug valve. (Note the two side plugs lettered A). These plugs act as bearings for the disc carrier pin. Should the movement of the pin cause the plugs to become worn, they can be replaced, saving the body and making the check as good as new. The double plug type check has another advantage over the single plug type. When mounted in a wall pipe it is always possible to take the valve apart, as one plug is always accessible. The top plug (also letter A) is also removable for insertion of screw-driver when regrinding is necessary. This feature eliminates the necessity of removing the valve from pipe line when repairs are necessary.

Cut No. 3

Shows sectional side view and illustrates to advantage the liberal thickness of metal in diaphragm. (See letter D), also the even distribution of metal throughout. All Genuine Penberthy Checks bear our trade-mark and the registered pressure 200 lbs. is also cast on each.

For Superior Checks specify Penberthy.

PENBERTHY INJECTOR CO., Limited, Windsor, Ontario

Steel Plate Work

WE have made a success of building Steel Plate Work by specializing in it.

The recent extensions to our shops have placed us in a better position than ever before to do this work. Our facilities in every department have materially increased—we have the men, the equipment, and the experience to turn out this special work as it should be.

We design and build any size of:—

Conveyors and Elevators
Smoke Breechings
Steel Stacks
Spark Arresters
Steel Buckets
Steel Tanks
Storage Bins
Cookers and Digesters
Steel Gas Mains
Refuse Burners

Before you buy anything along these lines, send us your sketch and let us quote.

JONES UNDERFEED STOKER

Cuts the Fuel Bills

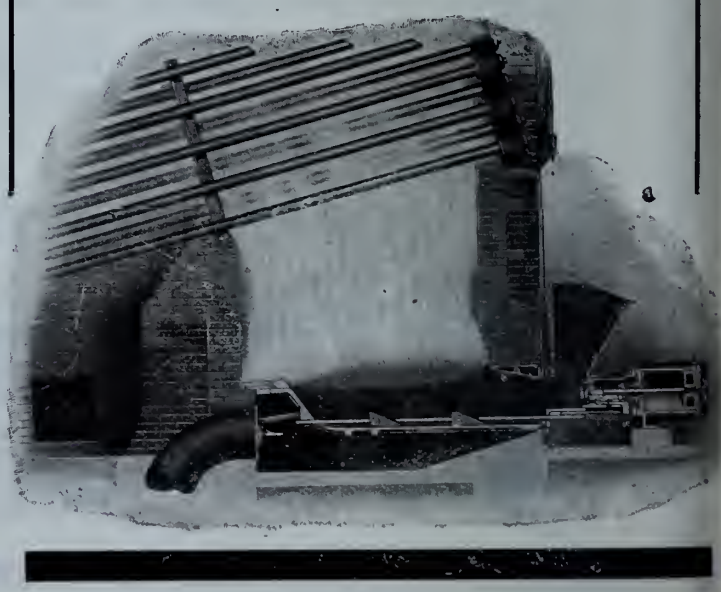
No Waste of Coal

Advancing fuel prices should influence you without further delay in installing the Jones Underfeed Stoker. Saves at least 15% in fuel—in many cases it will save 25%.

Simple in construction but thoroughly efficient. No complicated parts to cause trouble. No grates to lose coal through. They respond instantly to load fluctuations and automatically maintain a uniform steam pressure.

Does the smoke by-law affect you? The Jones Stoker prevents smoke.

Jones Underfeed Stoker Co.
LIMITED
37-41 Britain Street, TORONTO



Try a barrel of this great

Boiler Scale Remover and Preventive

Boico SAVES FUEL, OIL AND PACKING. It will rid your boiler of every bit of scale and of course prevent further formation.

BOICO is a faultless worker. Will not injure packings or valves in the slightest, or carry over in steam, or foam or prime. Contains nothing injurious whatsoever.

SEND FOR FREE TRIAL OF BOICO

Patent Anti-Clinker Shell Bar Grates

New Idea in Grates that Saves Time, Labor and Fuel

Fifty per cent. of the total surface is air space. This abundant air supply commands a perfect combustion which adds 25 per cent. more heat to the fuel gases and prevents clinker formation; the fact of there being no clinkers and an abundant air supply is a guarantee of greater heat from less coal.

Lessens clinker formation. Always clean. Burns slack, coal, coke or wood. By pressing lever grates are turned to new burning surface, breaking up coal and clinkers, leaving a clean fire.

Grates cannot twist or warp—Two grates in one.

War-Time Economy—

If you are anxious to practice some war-time economy, here are some other lines worthy of your attention:—

P.P.P.—Daniel's P.P.P. and Ebonite Packings for all Pressures. Only packing backed with scientific proof that it reduces friction. Long tests by Mechanical Engineers proved that P.P.P. saves 75% or more friction losses. Automatically regulates bearings on rod to requirements.

Tip-It Patent Welding Process. Scarcity and high price-speed steel compels rigid economy in its use. TIP-IT welding makes it possible to obtain tools with carbon shank permanently united to cutting tip of high-speed steel.

Copper Asbestos Boiler Gaskets—most successful boiler gasket made. They never blow out and never stick. Made of corrugated copper with pure asbestos, cord filled corrugations. Use them and end all leaks in pipe lines.

Write for prices and full particulars.

Murphy AUTOMATIC Furnace

DO IT NOW!

If you are firing coal under hand-fired conditions you *can increase capacity* 25 *to* 50 *per cent. without sacrificing efficiency*—by installing MURPHY STOKERS.

If you will equip with MURPHY STOKERS *you can reduce coal cost for power about* 25 *per cent.!*

If plant is operated on a three or four firemen basis, each shift, with MURPHY STOKERS *you can save* 25 to 33 per cent. of that annual cost.

Determine *annual coal and firemen costs;* 25 per cent. of that will approximate the dividend earning power of money investment required for MURPHY STOKERS.

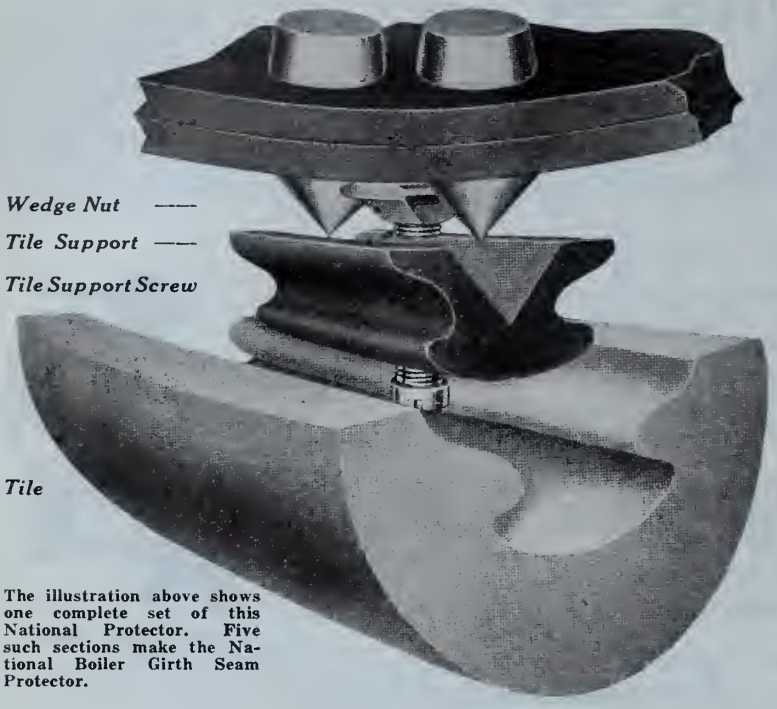
The National Boiler Girth Seam Protector

Patented U.S.A. October 25th, 1916 **Foreign Patents Applied** **Patented Canada May 29th, 1917**



The illustration above shows one complete set of this National Protector. Five such sections make the National Boiler Girth Seam Protector.

The Only Perfected Device which prevents

Fire Cracks and Leaks on all Steam Boilers

It is needless to say that the manufacturers of Horizontal Boilers have been charged with the failure of the seam, which has not been any fault of theirs, for they have been directing their attention toward a remedy; and the only solution seemed to be a single shell on the bottom, but that construction has been a failure.

If you are now using H. T. Boilers, you are aware that the seam is a great deal of trouble, owing to crystallization and fire cracks. These are due to the intense heat concentrated against this particular piece. The lapping of the plates makes the distance from the inside of the boiler too great for the water to keep the outer lap sufficiently cool; therefore, the constant opening and shutting of the fire-doors allows the cold air to rush into the fire-box, causing violent expansion and contraction of the outer lap.

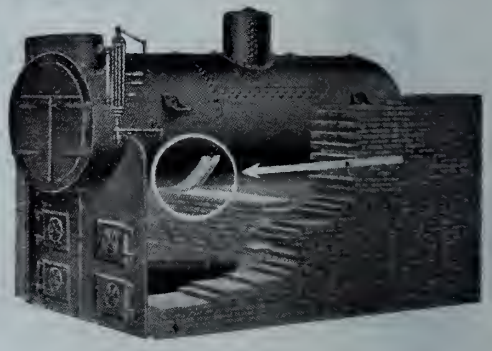
Our National Girth Seam Protector will overcome this difficulty, and will protect your seam from fire-cracking or leakage at this point.

If your girth seam is giving you trouble at the present time, have the seam caulked up, attach one of these Protectors and the seam will remain absolutely dry thereafter.

If your Boiler is not Fire-cracked it eventually will; prevent this by putting on a National Boiler Protector. You will save cost in repairs and prolong life of the boiler. All new boilers should be Protected.

Write to-day for our catalog giving names of many users of the National Boiler Girth Seam Protector and what they say about it.

Made in Canada.



The illustration above shows one complete set of this National Boiler Protector installed. Indorsed by Engineers and Boiler Inspectors and by Insurance Companies. So simply constructed is this National Protector that any fireman can attach it in 30 minutes.

JOHNS-MANVILLE

Packings that pay dividends

A horsepower at the cross-head costs more than one at the coal pile. All your plant charges such as firing, oiling, superintending, overhead, all combine to increase it.

Heat unit for heat unit, power saved in steam is a bigger saving than power saved in coal. And the further you go into the plant the greater is this difference—the more this is true.

So that rod friction in a pump, an engine or compressor is a sizable item. Piston leaks and flange losses are not only nuisances but costly ones. Shut-downs are worse because production stops, but expense keeps going while economy takes a vacation.

All these things prove the importance of packing. All these things demand the use of good packings in materials and in design. Packings that "go dead" in the stuffing box are the finest rod brakes in the world. They ask you to slow up the engine to stop a leak.

Packings of shoddy materials wear out and establish the shutdown as a plant institution. Packings that give real service have been designed by stuffing box engineers. They have been built to minimize all common packing faults. You will recognize them by their first name, Johns-Manville. Their last name differs because of the variation in the work they are fitted for.

Here they are a standard line that covers every packing requirement:

Johns-Manville Sea Rings
Johns-Manville Service Sheet Packing
Johns-Manville Kearsarge Boiler, Man and Handhole Gaskets

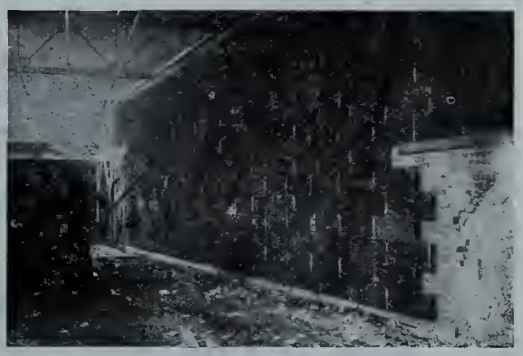
The Economy of an Ice Storage

Most ice plants (except in the far South) operate under heavy overload during the summer months, at reduced capacity in the spring and fall, and shut down entirely during the winter. Now, if these plants had suitable ice storages, insulated with

Nonpareil Corkboard Insulation

For All Cold Storage Rooms

their machines could be operated at nearly uniform capacity the year round, except when repairs were being made.



Insulating an ice storage room with Nonpareil Corkboard. Tropical Ice Company, New Orleans, La.

The slack season would be utilized for filling the storage. The expensive method of operating at less than capacity would be eliminated. The men would have steady employment; it would not be necessary to break in a new force in the spring. And then, when warm weather came, the reserve supply of ice would be used to take care of the large demand.

A properly designed ice storage, insulated with Nonpareil Corkboard, is a paying proposition.

Why not ask for information? It is free.

Armstrong Cork & Insulation Co., Ltd. 504 McGill Building Montreal, Que.

Measuring Direct Returns

EVERY advertiser is entitled to know what he is getting for his money.

Every publisher is anxious that his paper shall be credited with the returns which it produces.

Yet the fact of the business is that it is next to impossible to trace all of the results of advertising. Direct returns as a measure of the value of space are therefore inadequate, and fail to indicate the accomplishments of the advertising.

This is indicated in a particularly convincing way by the experience of a well-known book publisher, whose business is handled entirely by mail, and is therefore altogether the product of advertising.

All ads published are keyed; direct advertising is likewise watched carefully, with special key numbers, so as to enable the publisher to note the percentage of returns from each piece of advertising sent out.

In spite of all this, however, the business which can be definitely attributed to specific forms of advertising is only about fifty per cent. of the total.

In other words, at least half of the business cannot be credited at all, and yet without any question it is the result of advertising, because all of the business of the house is secured in this way.

As a result of his experience, this book publisher now multiplies the direct results of advertising by two in order to get a line on the complete results.

Most advertisers in other fields would probably be able to use a larger multiple, especially if they have salesmen and are following up their advertising in other ways, because in that event the situation is complicated by the opportunity for personal solicitation to interpose and take up the work where it was left off by the printed advertisement.

Consequently, when an advertiser says he didn't get results, an analysis of his business would probably demonstrate that results were secured, but were not credited to specific media.—*Class.*

High Pressure Air Compressor Design and Application*

By Joseph M. Ford

Compressed air at high pressure is becoming an increasingly important medium in modern engineering practice and in naval warfare. The accompanying paper deals with the machines which produce high pressure air, leaving on one side the question of power transmission by compressed air. In passing, the principal advantages of this system are referred to, and will be seen to be of considerable value. They consist of the facility with which energy can be stored; the unlimited rate at which accumulated energy may be converted into useful work; and, apart from loss of efficiency, leakage cannot cause any awkward consequences.

TESTING MULTI-STAGE COMPRESSORS

ALTHOUGH extremely interesting results can be obtained from scientific tests of air-compressors, the manufacturer is usually content with tests for the efficiency of the machine. A purchaser requires to know the power required per cubic foot of air actually delivered, since this is the basis of comparison for compressors. The problem, then, is to determine exactly how much air is being delivered. The two methods usually adopted are: the "pumping-up" method and the orifice test. In the former the compressor is run at its full pressure, pumping into a reservoir, and from this latter the air is led to a receiver of known capacity. The details of the method are well known, being exactly the same in principle as used on tests of ordinary compressors for pneumatic tools. The orifice test is now being largely adopted, on account of the possibilities of error with the "pumping-up" method due to inaccurate temperature readings, oil and water in the bottles, etc. The orifice test method is also well known in connection with ordinary compressor work and need not be described.

Useful information as to the condition of piston rings and valves may be obtained from indicator cards, which also show to some extent the efficiency of the cooling. If, on applying Brauer's construction to the diagram, the compression line is found to be almost isothermal, it does not necessarily indicate that the cooling is almost perfect, as is sometimes stated. The line may indeed appear to be the isothermal, due almost certainly to leaky piston rings or suction valves. Lines giving an exponent value in PVn of less than 1.26 should be looked upon with suspicion.

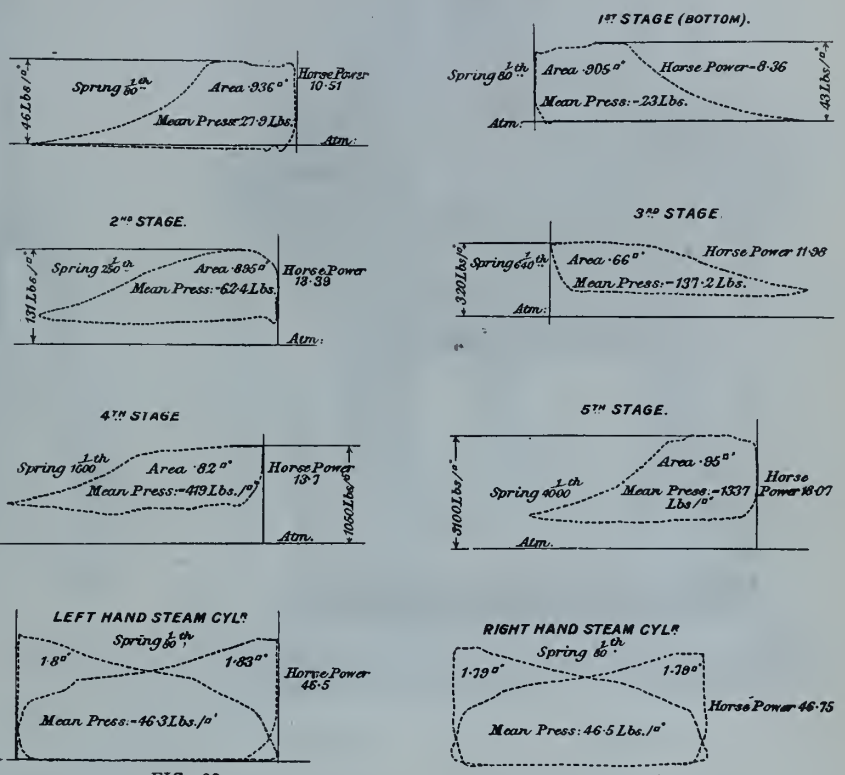

FIG. 32a. FIG. 32b.

If any stage pressure is very much above that estimated, the trouble will likely be due to the valves of the next higher stage leaking, or to its own delivery valve not being tight. Judicious use of the cylinder drain cocks, and the behavior of the stage pressure gauges immediately on shutting down, enables conclusions to be drawn as to the source of trouble without the necessity of taking indicator cards.

Maintenance of Compressors

The usual practices of engine maintenance apply to compressors, but unfortunately the care and attention given to these machines is frequently less than that necessary. Particularly is this the case in some Diesel engine plants, where the compressor, until it gives trouble, is looked upon as an engine detail. The lubricating system, above all, must be kept in the highest state of efficiency, as failure in, say, the high-pressure stage, where these is usually considerable ring friction, generally leads to a cracked

*Conclusion of paper read before the Greenock (Scotland) Association of Shipbuilders and Engineers. See issues of May 31 and 28 for previous instalments.

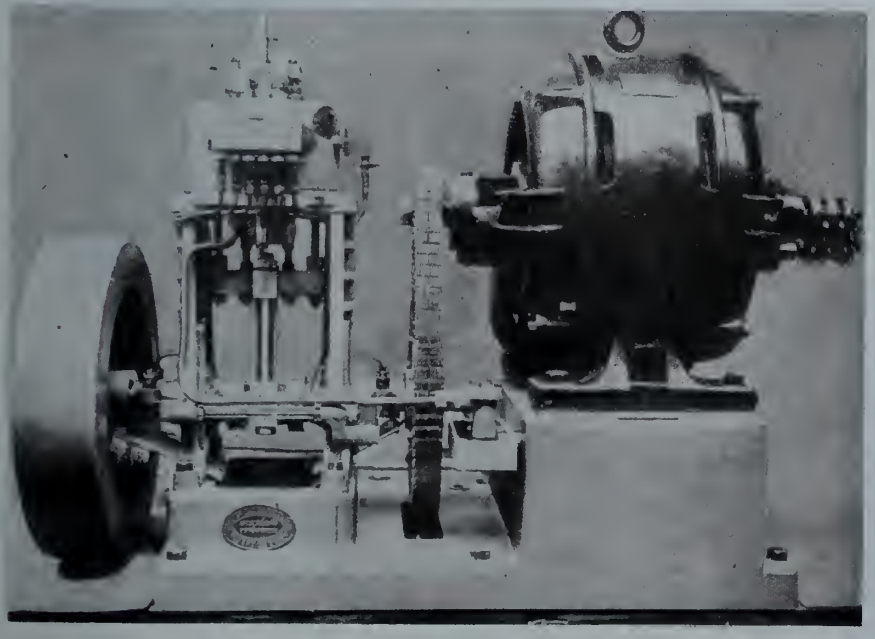

FIG. 30. "BROTHERHOOD" THREE-STAGE COMPRESSOR, 600 CU. FT. CAPACITY.

cylinder, which may not be the limit of the damage.

When the circulating water is chalky or muddy, the cooling system must be periodically cleaned if the highest efficiency is to be maintained. Valves should be examined from time to time for cracks. It is of the utmost importance that relief valves should be in perfect order, for these are in every way as important as a boiler safety valve, and under no conditions whatever should the valves be wedged or otherwise put out of operation to stop a leak. They should be tested for blowing off at frequent intervals. If stage pressures are rather higher than normal, it means probably, as previously explained, that valves are leaking.

Provided the pressures are not excessive, no trouble will result from running in this condition, but matters should be put right at the first opportunity. In justice to Diesel engine air-compressors, it must be stated that the frequency with which the engine log book records "compressor trouble" is due in many cases to negligence. There is still a big scope for improvement in the design of multi-stage compressors.

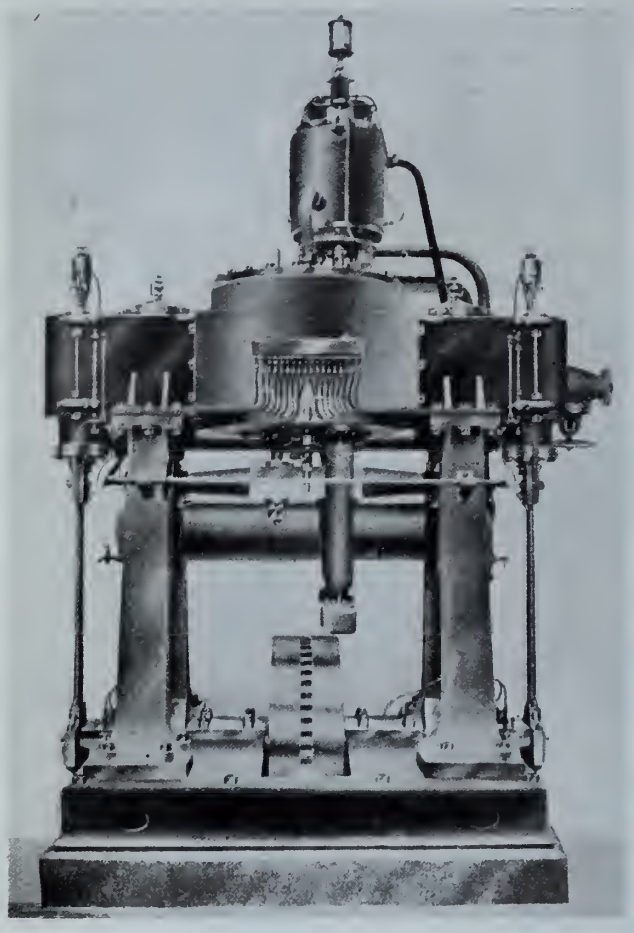

FIG. 31. "BROTHERHOOD" FIVE-STAGE COMPRESSOR, 10,000 CU. FT. CAPACITY.

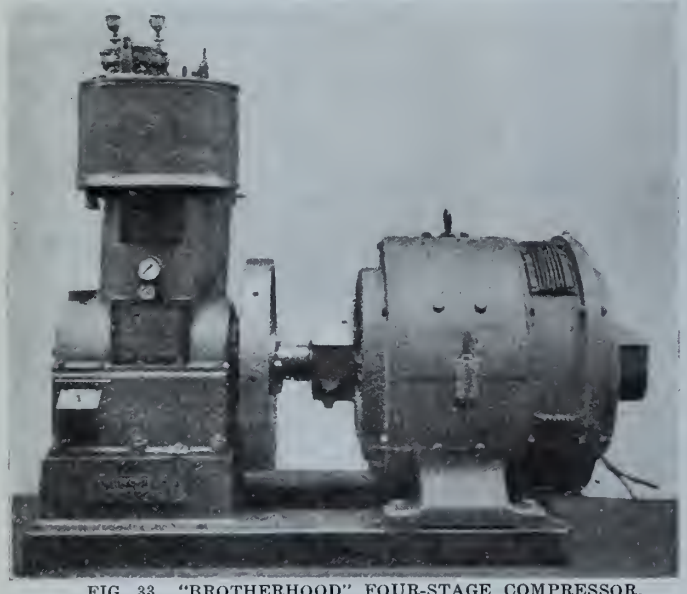

FIG. 33. "BROTHERHOOD" FOUR-STAGE COMPRESSOR.

Modern Machines

Through the courtesy of various makers it has been possible to reproduce several photographs and drawings of some of the latest high-pressure air-compressors, and a glance at these will show at once the divergence which exists in design.

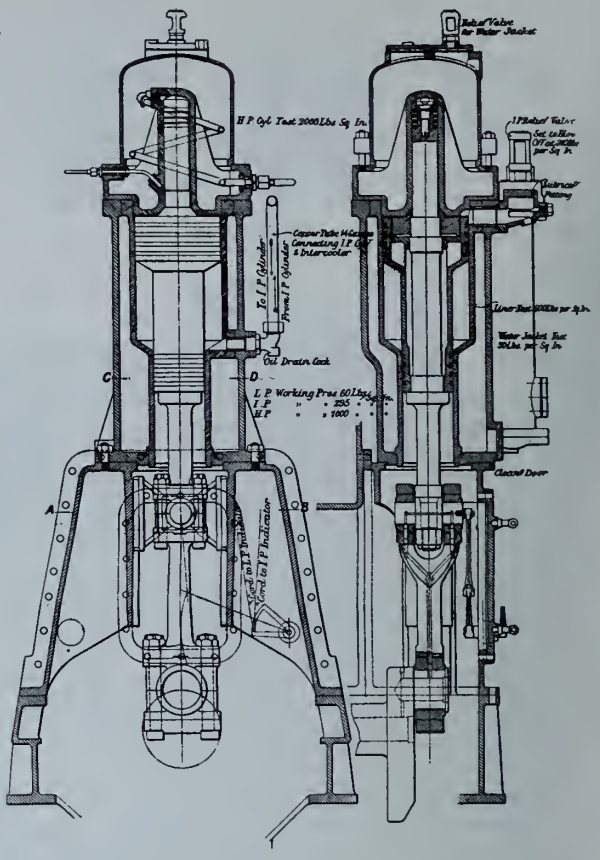

FIG. 35.

FIG. 36.

Fig. 30 shows a small three-stage compressor, chain-driven, and having a capacity of 600 cubic feet of free air per hour, compressed to 3,000 lb. per square inch. As has been already explained, in small machines the tendency is to reduce the number of stages of compression for a given final pressure, and this statement is borne out by a comparison between this machine and that shown in Fig. 31.

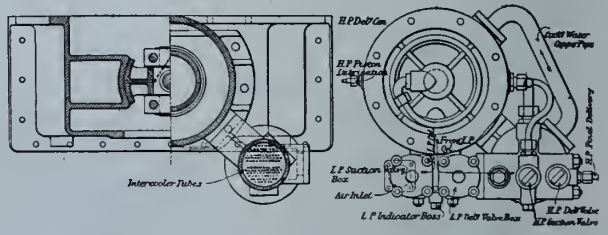

FIG. 37.

FIG. 38.

Although the working pressure of this latter is the same, viz., 3,000 lb. per sq. inch, the capacity is 10,000 cub. ft. free air per hour, or more than 16 times as great as that of the small machine, and in this case the compression is divided into five stages. The machine is steam-driven, two double-acting steam cylinders being at the ends and the air cylinders in the centre, while the air piston rods are coupled side by side to the horizontal bridle which is attached at its extremities to the steam line crossheads.

A complete set of indicator diagrams from this machine is given in Figs. 32 A and B. It may be mentioned that the shape of the suction lines in the cards from the fourth and fifth stages results from the fact that the cylinder volumes are fairly large compared with the cubical contents of the intercoolers, the lowest point on the line indicating the commencement of transfer. The comparatively small clearance volume in the first stage cylinders, shown by the rapid drop in pressure on the back stroke, is also worthy of note, the reasons for the small volume having previously been discussed.

Fig. 33 shows a four-stage direct-coupled machine by the same builders, capable of charging a 45 cub. ft. reservoir to 2,000 lb. per sq. inch in 80 minutes when running at 250 r.p.m., whilst the five-stage direct-coupled machine shown in Fig. 34, charges a 40 cub. ft. receiver to 3,000 lb. per sq. inch in one hour at 350 r.p.m.

A point to which attention may be directed is that the intercoolers on these machines are generally of the submerged type, that is, the cooler consists of a copper or steel pipe coiled round the cylinders in the tank. This tank construction simplifies very considerably the cylinder castings, and the cooling effect is probably enhanced due to the whole of the connections being submerged, but of course this method is not always admissible. The cooling is still further improved by water injection, the water in the case of a steam-driven machine being obtained by condensation, and therefore quite free from foreign matter.

The piston packing in these compressors is of the fibre-ring type, the high-pressure gland fibres being fitted in removable boxes, which can be repacked at the bench—an obvious advantage. All valves, which are mainly of the thimble type, have removable seatings, so that a replacement is readily effected.

An unusual feature is the provision of an indicator to show that the circulating water is flowing through the casing, which in many cases is very convenient, as it is not always easy to arrange for the water to be discharged into a funnel. The importance of maintaining the circulation will be readily understood from a study of the temperature charts previously given.

Diesel Engine Compressors

Special attention has been devoted to the design of air-compressors for Diesel engines; product of one firm ranging from small hand-driven machines for charging starting bottles in case of emergency, to those used on some of the largest machines yet constructed. A patented design of three-stage compressor for 1,000 lb. per sq. in. working pressure, which has given very satisfactory results from marine work, is shown in Figs. 35 to 38, a special feature of this machine being the arrangement of the second or intermediate stage. By suitably proportioning the cylinder and intercooler dimensions it is possible to dispense entirely with valves in this stage, which means that the intercooler volume is part of the intermediate pressure cylinder clearance.

The principle will perhaps be better understood by reference to Figs. 39 and 40, which shows the "Reavell" patent V class duplex compressor. The air is delivered from the low-pressure stage down through the intercooler to the second stage cylinder, and on the down stroke it is compressed, and again passes up through the same intercooler on its way to the high-pressure cylinder—the high-pressure suction pipe being in direct connection with the low-pressure delivery passage. The only modification to the low-pressure valves which this entails is that the valve cover must be arranged to withstand the intermediate pressure delivery pressure instead of the low-pressure as is usual.

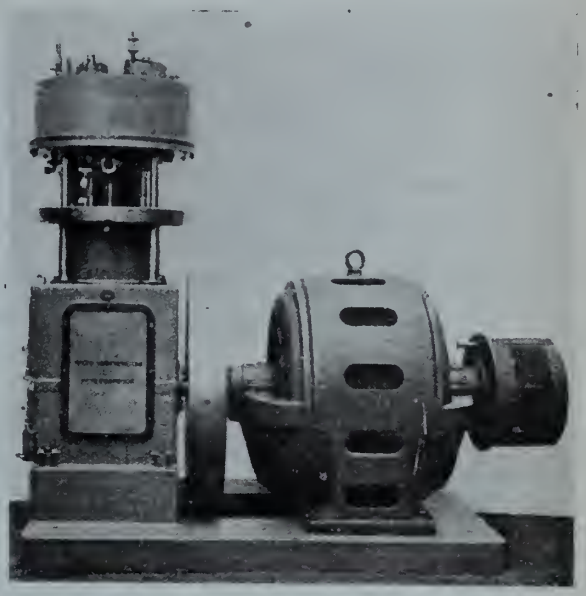

FIG. 34. "BROTHERHOOD" FIVE-STAGE COMPRESSOR.

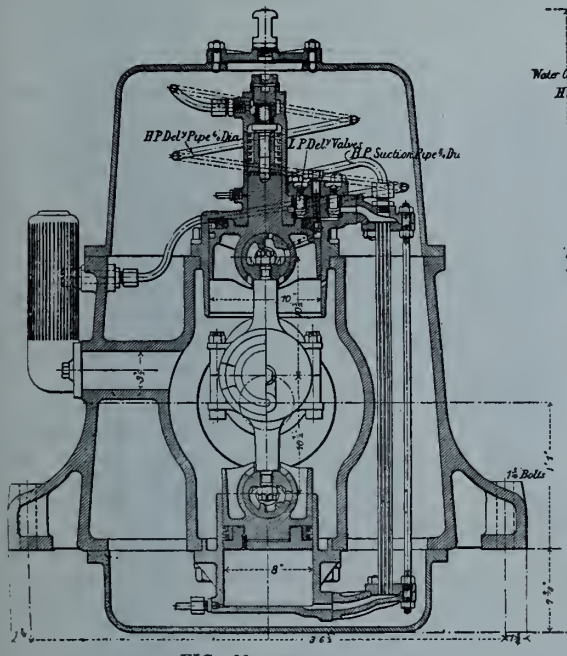

FIG. 39.

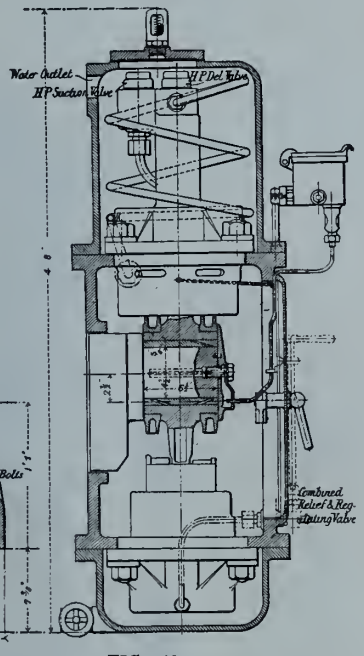

FIG. 40.

Since the air passes through the same intercooler twice, only one of these is required, instead of two as with other designs, and apart from the simplicity of construction resulting therefrom, the efficiency is considerably increased owing to the fact that the second stage of compression is effected in the cylinder and cooler itself—the reasons for improved efficiency having already been dealt with. The marine compressor under consideration is exactly the same in principle, only a single intercooler being provided.

In the remarks on cylinder clearance volume, it was pointed out that in a Diesel engine compressor it is sometimes advantageous to have considerable cylinder clearances, and this is borne out by a study of this machine. The clearance volume in the low-pressure stage is, of course, reduced as far as possible, the method of securing the piston to the rod being such that the clearance space is the minimum. The intermediate-pressure clearance, however, is very large, being, in fact, the whole volume of the intercooler tubes and connecting pipe; whilst the high-pressure clearance is also very large, being the volume of the coiled aftercooler in the jacket. Apart from the features which have already been dealt with in the notes on clearance, this arrangement allows the high-pressure valves to be located outside the water jacket—a distinct advantage—but, further, the air is cooled to a large extent after compression before it cooled to a large extent after compression before it reaches the delivery valve, which cooling undoubtedly lengthens the life of the

latter and reduces carbonization troubles. The theoretical indicator diagram which results from these large clearances and "valveless intermediate" construction is

FIG. 42.

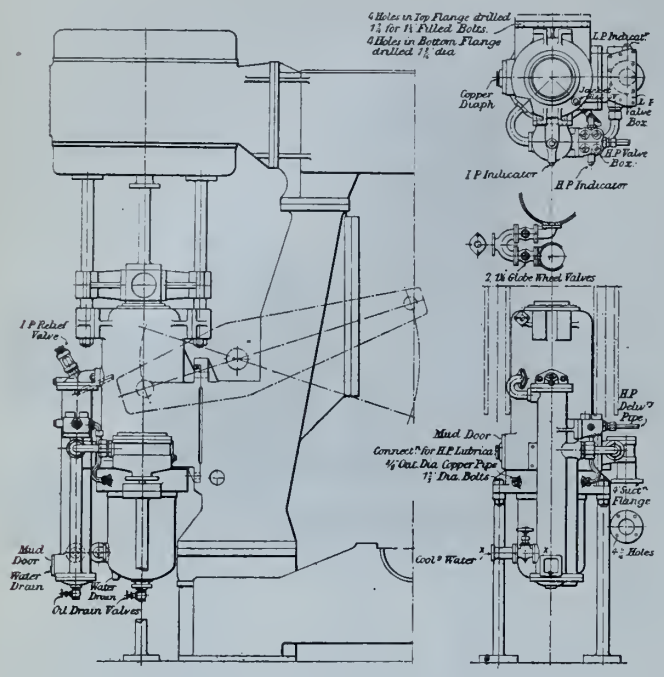

FIG. 41. FIG. 43.

cracked, it might prove a little difficult to remove the sleeves so as to permit the withdrawal of the liner. This compressor is driven from the forward end of the engine crank shaft, and the stage pressures adopted in this case are: low pressure 60 lb. per sq. inch, and intermediate pressure 295 lb. per sq. inch, when working at its full capacity against a final delivery pressure of 1,000 lb. per sq. inch.

In modern high-power marine Diesel engines of the two-cycle slow-running type, it has become usual, for various reasons, to drive the scavenging pumps by means of levers, in accordance with

Figs. 41 to 44 show the compressor arrangement which has been successfully adopted on a large British marine engine, whilst sections of the machine itself are given in Figs. 45 to 47. This compressor also embodies the Reavell "Valveless intermediate" patents, the direct passage between the intermediate-pressure cylinder and the intercooler being clearly shown in Fig. 46. The simple construction of the intercooler is worth noticing, the tubes, which are usually of copper, being expanded into the steel tube plates. When the thickness of the latter, gauge of the tubes, and method of expanding are carefully chosen, this system leaves little to be desired, and, further, it permits of a greater cooling surface being obtained, for the same overall dimensions, than would be the case were the usual ferrule system adopted. However, the tubes must be of the highest quality material and must be thoroughly tested before use, for should a tube failure occur, it would be more difficult to repair than in the case of a cooler with ferrules.

FIG. 46.

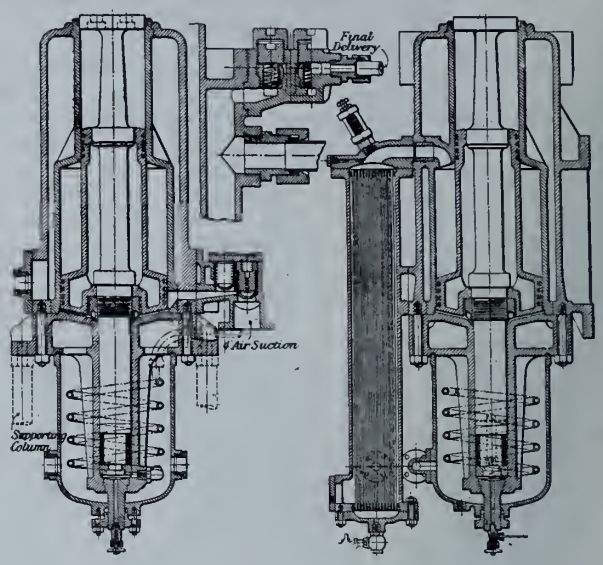

FIG. 45. FIG. 47.

The valve arrangements are seen in Figs. 45 and 47, the low-pressure suction and delivery valves being interchangeable, whilst the high-pressure valves, which have removable seats, are also interchangeable. This, of course, reduces the number of spares which have to be carried, in addition to obviating the possibility of mistakes when reassembling after an overhaul.

To minimize the danger, should the high-pressure cooling pipe or any other part under pressure give out, three large bursting diaphragms are provided on the water jacket (two being on the high-pressure bonnet, and one on the opposite side of the low-pressure valve box); these are ruptured, thus giving free egress to the water and air, when the pressure in the jacket exceeds a pre-determined figure. It may be remarked that the arrangement of this compressor, with the high-pressure cylinder at the bottom, is unusual, and to avoid difficulties which might otherwise result from accumu-

given in Fig. 54, annexed, and applies to all machines of this type.

As far as the actual construction of the machine is concerned, attention may be called to the very effective cylinder jacketing, especially at the breech end of the low-pressure cylinder; also the simplicity of the high-pressure cylinder casting, with its absence of valve pockets, should be noted. It might be noted that one small point which is open to criti-

FIG. 48. FIG. 49. FIG. 52. FIG. 53.

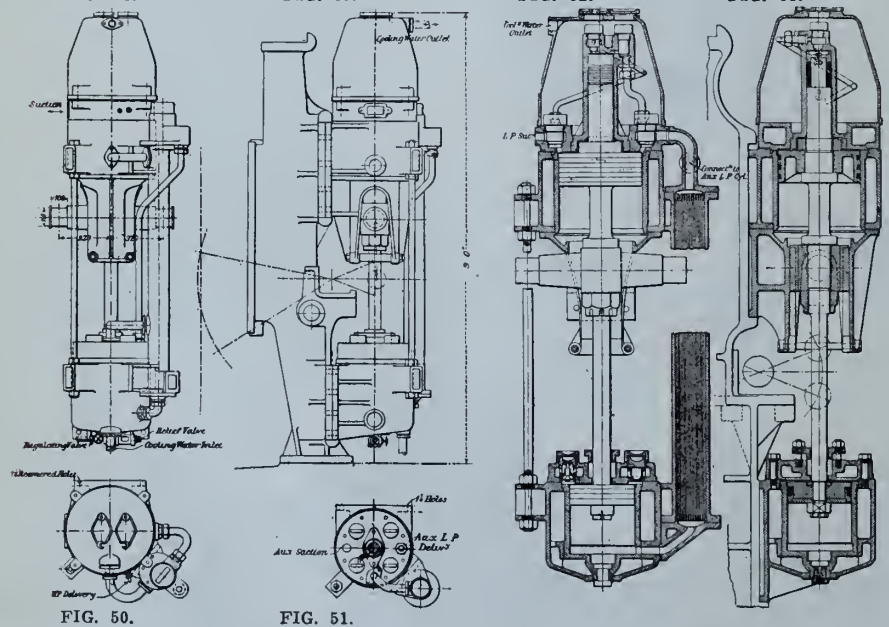

FIG. 50. FIG. 51.

cism is the method of making the air connection between the jacket and the liner —viz., by the forced-in sleeves, for should a liner by any chance become scored or the well-known marine practice, and in many cases the compressor drive can conveniently be arranged in conjunction therewith.

lated oil in the latter, special provision is made for draining.

Another lever-driven compressor as used on engines of continental design, is shown in Figs. 48 to 53, and, as in the previous machines, there are no valves in the second stage. In this case the intermediate-pressure cylinder is located below the crosshead, and a patented

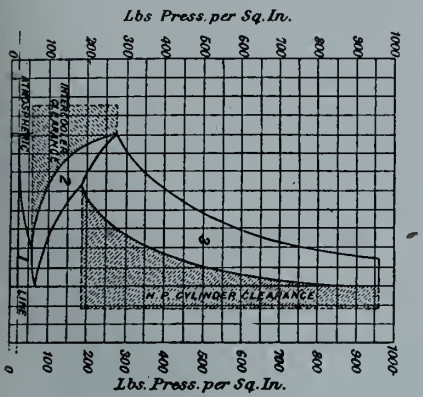

FIG. 54.

pressure cylinder, the whole then passing to the intermediate cylinder in the usual way. By this simple means, the capacity of the compressor can temporarily be increased by about 30 per cent., which means that it will not be necessary to keep such a large auxiliary machine running as would otherwise be the case. As

pedo work, for a delivery pressure of 3,500 lb. per sq. inch. The capacity at this pressure and 340 r.p.m. is 30 cub. ft. of free air per hour. The machine is a four-stage steam-driven type and is a self-contained unit, the inverted steam cylinder, as will be seen, being placed beneath the air cylinders. Apart from

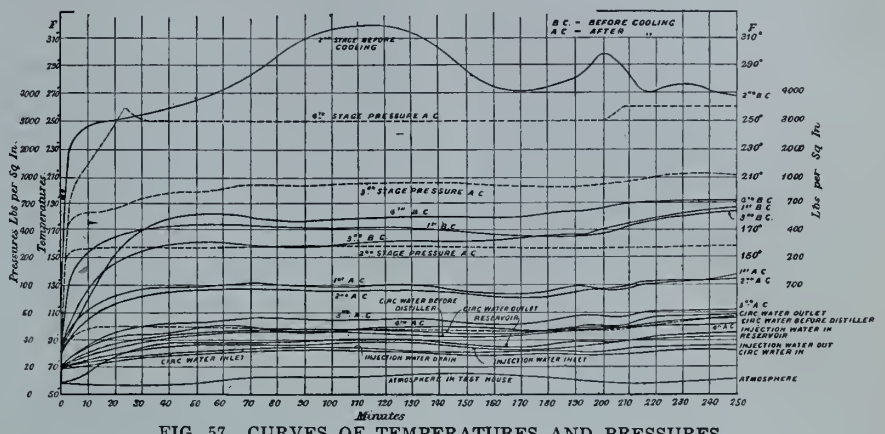

FIG. 57. CURVES OF TEMPERATURES AND PRESSURES.

feature is the utilization of the end of this cylinder as an auxiliary low-pressure cylinder. Normally the valves in the cover of this cylinder are inoperative, but when there is considerable manoeuvring, and in consequence a big demand for air, such as obtains on entering port, they can be brought into action, either automatically or by hand, when, as will be seen from the sections, this cylinder delivers air into the top of the intercooler at the same time as the main low-

would be expected, very special attention has to be paid to the proportioning of such a machine, on account of the alteration to the distribution of the total work which results from such a device. In this particular machine the high-pressure valves are arranged directly in the cylinder head, access to them being obtained from the engine upper platform through the small covers on the bonnet.

Fig. 55 shows a well-designed machine of a type similar to those used for tor-

the very compact arrangement which is thus obtained, the drive is direct, so that the stresses in the connecting rods, for example, are much less than they would be with the "side-by-side" arrangement. Another noteworthy feature in the design is the provision of a separate cylinder for each stage of compression, instead of having recourse to differential pistons, which latter arrangement, although possessing many advantages, is decidedly inferior from a thermal point

of view, on account of the reduced cooling surface per unit of heat generated. In addition to the effective cooling resulting from the arrangement adopted, intercoolers are provided, and, further, a distiller is fitted which provides pure water for injection into the air cylinderss.

Figs. 56 and 57 and the table show the results of an exhaustive trial carried out by the builders on one of these machines. The curves reveal many points of interest, whilst an idea of the distribution of work through the machine can be obtained from the cards, which show a mechanical efficiency of about 68 per cent.—a very satisfactory result considering the large amount of piston friction and the two connecting rods, etc. The card from the fourth stage would seem to indicate a large cylinder clearance, but it may be pointed out that sometimes the indicator itself adds quite a large percentage clearance to a small high-pressure cylinder—especially when connections are long, due to the necessity of passing through a water jacket. Regarding the intercooling effect as shown by the curves, it might be thought that improvement could be effected. In practice, however, a long continuous run at full pressure is very seldom required of compressors of the charging type—therefore the intercoolers need not be of such dimensions as those required for a continuous duty machine. Again, the question of economy is of less importance.

With the increasing number of applications of high-pressure air, and especially with the growth of the Diesel engine industry, more attention is being paid to the design of high-pressure machines, and in view of the scarcity of trustworthy literature on the subject, the foregoing brief outline of some of the points which arise may serve a useful purpose.

WOOD FUEL VS. COAL

THE fuel value of two pounds of wood is roughly equivalent to that of 1 pound of coal. This is given as the result of certain calculations made in a Government forest service laboratory, which show also about how many cords of certain kinds of wood are required to obtain an amount of heat equal to that in a ton of coal.

Certain kinds of wood, such as hickory, oak, beech, birch, hard maple, ash, elm, locust, longleaf pine, and cherry, have fairly high heat values and only one cord of seasoned wood of these species is required to equal one ton of good coal. It takes a cord and a half of shortleaf pine, hemlock, red gum, Douglas fir, sycamore, and soft maple to equal a ton of coal, and two cords of cedar, redwood, poplar, catalpa, Norway pine, cypress, basswood, spruce and white pine.

Equal weights of dry, non-resinous woods, however, are said to have practically the same heat value, regardless of species, and as a consequence it can be stated as a general proposition that the heavier the wood the more heat to the cord. Weight for weight, however, there is very little difference between various species; the average heat for all that have been calculated is 4,600 calories, or heat units, per kilogram. A kilogram of resin will develop 9,400 heat units, or about twice the average for wood. As a consequence, resinous woods have a greater heat value per pound than non-resinous woods, and this increased value varies, of courdse, with the resin content.

The available heat value of a cord of wood depends on many different factors. It has a relation not only to the amount of resin it contains, but to the amount of moisture present. Furthermore, cords vary as to the amount of solid wood they contain, even when they are of the standard dimension and occupy 128 cubic feet of space. A certain proportion of this space is made up of air spaces between the sticks, and this air space may be considerable in a cord made of twisted, crooked and knotty sticks. Out of the 128 cubic feet, a fair average of solid wood is about 80 cubic feet.—"Canada Lumberman."

COAL PRODUCTION IN CANADA

REPORTS from the principal coal mine operators in the Dominion for the six months ending June 30, last shows a total coal production of 6,154,420 short tons. Nova Scotia led all other provinces with a total of 3,058,216 tons. Alberta was second with 1,763,506 tons and British Columbia third with 1,100,100 tons. Exports averaged around 130,000 tons per month, and were considerably lower than for the same period a year ago. Total production for 1916 was 14,483,395 tons. Bituminous imports for the first six months of the year were 6,392,378, compared with 5,848,289 for the same period a year ago. Anthracite imports up to June 30, 2,231,857, and for the corresponding period last year 2,097,151.

Total coke production in Canada for six months was 580,997. Imports were 490,830, and exports 8,905. Production of coke includes only the coke made in bee-hive or by-product ovens and does not include coke made by gas companies in retorts.

RECENT activities of the Society for the Promotion of Engineering Education included the publication of an article on "Technical Book Writing," by J. A. L. Waddell, consulting engineer, Kansas City.

ENGINE-HOUSE EFFICIENCY

By L. E.

AN important difference is to be observed between the boiler house and the engine house as regards the securing of maximum efficiency. In the boiler house, once the design of the plant is satisfactorily settled, everything depends upon the operator. In the hands of a skilful fireman an ill-designed plant may be made to give quite passable results; in the hands of an unskilful fireman the best plants may show a deplorably poor efficiency. Even with mechanical stokers the personal factor is important; with hand firing it is also important. But when one passes from the boiler-house to the engine-house the order is reversed; the determining factor is here the machine rather than the man. If the engine is well designed for the load, and conditions which it has to meet, if the loads on the cylinder are well proportioned, and the valves correctly set, then the engine when set to work will give of its best without any large amount of supervision or alteration by the engineer. Care must, of course, be exercised in seeing that lubrication is perfect, the cylinder must be indicated regularly, to see that the valves are in correct adjustment, and slight alterations made accordingly; the valves and piston must also be tested regularly for steam tightness.

Generally speaking, however, the operations going on in the engine are entirely automatic, and do not require the constant control of the engineer. The normal operation of the engine on which the steam consumption depends is out of the control of the engineer after he has correctly adjusted the parts. For these reasons, power plant owners, while taking care to have good design and skilled operation in both departments, should give especial attention to the machine in the engine room and to the man in the boiler-house.

Engine Losses.

The efficiency problem in the engine-room is mainly one of installing machinery so designed and constructed as to convert the energy in the steam received from the boiler-house into the greatest measure of mechanical power, which means the least losses of heat between the steam inlet valve and the rim of the flywheel.

It has been determined that of the total heat in the fuel, something like 41 per cent. is lost in the engine. This loss is comprised, as to a very small part, of engine friction and radiation; the bulk of it is accounted for by the heat that passes away in the exhaust steam to the condenser. This latter loss is for the most part unavoidable, being due to the limited range of temperature within in which it is possible to work without resorting to expedients more costly than any economies to be effected. With an average modern engine working under good conditions, using steam at 100 deg. superheat and discharging into an efficient condenser, something like 11½ lb. of steam per indicated horse-power will be used, which means that only 25 per cent. of the heat in the steam is turned to account as mechanical power. But between the absolute minimum of loss necessitated by the nature of the case and the loss which may occur in an engine which is badly designed, constructed and maintained a considerable margin exists, and it is for the power user to reduce this margin to the lowest figure attainable. In a paper read by Mr. John Ingham before the Yorkshire Association of Textile Managers, reducible heat losses in the engine-house were classified under the following heads:

(a) Leakage of steam past valve and pistons.

(b) Cylinder condensation.

(c) Loss due to large clearance.

(d) Loss of heat between the cylinders.

Valve Leakage.

Take first the loss due to leakage past the valve. Theoretically, when the valve has closed on its seating, no steam should enter the cylinder. Practically there is great difficulty in obtaining and maintaining a steam-tight valve. Whether the valve employed be a slide, Corliss, piston, or drop valve, some leakage takes place. Further, whilst the valve might be steam-tight when tested under pressure when stationary, slight distortions are possible when working, which will cause leakage. With well-bedded valve faces in good condition, the loss will not be much, but periodical tests should be made to ensure that all valves are reasonably steam-tight. Some leakage will similarly occur past the piston. Piston rings and cylinder liners will wear, and although many ingenious devices are in use for maintaining steam-tightness under difficult conditions, tests should be made and the parts examined regularly to make sure that the steam does its work without taking a short cut past badly fitting piston rings.

The loss due to cylinder condensation depends on the range of temperature in the cylinder, or the difference between admission and exhaust, and upon the time the cylinder surfaces are subjected to the lower temperature. Consider for a moment what happens in, say, a Corliss cylinder. Steam is admitted to the cylinder, and fills the cylinder up to say, 25 per cent. of the stroke with steam at, say 480 deg. Cut-off takes place, and steam is expanded down, and, at, say ⅞ of the stroke the exhaust valve opens, and the steam passes away to the low-pressure cylinder at a reduced temperature. During the rest of the forward stroke, and up to almost the end of the return stroke, the exhaust valve remains open, and the cylinder walls are subject to the cooling effect of the low-temperature steam. Consequently on the next admission of steam a certain proportion of the heat in the steam is expended in heating up the cylinder walls. The remedy for this is to reduce the temperature range in any one cylinder or to reduce the time during which the cylinder walls are exposed to the lower temperature.

Clearance.

Another factor to which loss may be due is large clearance spaces. The most economical engines, other things being equal, are those with the least clearance. With the piston at one end of the cylinder closed, the space between the back of the pistons and the cylinder cover, and the passages from the valves to the cylinder, must be filled with steam every stroke, and although cushioning after the exhaust valve closes partly affects this, yet much new steam is wasted every stroke from this cause. Any design of cylinder which reduces the clearance space makes for steam economy.

There is, finally, the loss of heat which takes place between the cylinders in compound or triple-expansion engines. An examination of the combined diagrams from such engines reveals that material loss does occur at this stage. It can be reduced considerably by good design and care in covering, and by properly draining the connection between any two cylinders, but it can only be eliminated by allowing the whole of the expansion to take place in one cylinder. In all types of steam engines greater efficiency can be secured by close attention to these four principal sources of heat loss, but in what may be called the standard types of engine there are limiting conditions which prevent improvement beyond a certain point.

Uniflow Efficiency.

There is a type of machine, however, in which piston leakage, cylinder condensation, and clearance losses are reduced to a minimum, and between-cylinder losses are eliminated. This type, known as the uniflow type, was introduced into this country some six years ago, and has won steadily increasing recognition. Instead of exhaust valves, it has a ring of exhaust ports round the cylinder midway in its length, and as the piston reaches the end of its stroke it uncovers the port automatically, and allows a free escape of steam to the exhaust. The cylinder is much larger than in the standard design of engine, and the piston is about three times as deep as the ordinary piston . The steam cycle in the uniflow cylinder is fairly generally understood. The steam valve opens and admits steam expands in the cylinder as the piston moves formard. At a pre-determined point cut-off takes place, and the steam expands in the cylinder as the piston moves forward. When the stroke is nearly completed, the circular exhaust ports surrounding the cylinder are uncovered and the steam escapes to an annular chamber, which is cast round the cylinder ,and thence direct to the condenser. The area of the exhaust ports thus uncovered is many times greater than could be provided by any exhaust valve, and consequently the exhaust steam can be got away to the condenser rapidlv. As a matter of fact, the piston only just uncovers the open-

ings, and then closes them on its return stroke.

The period during which the cool temperature of the condenser is in touch with the cylinder walls is consequently about ⅛ of the stroke, as against ⅞ of a stroke in the ordinary form of cylinder. Compression, of course, commences immediately the ports are closed again, and is carried up to almost the initial pressure.

The heat economies in this type of cylinder are due mainly to two things; first, to reduced cylinder condensation resulting from the diminished time during which the cylinder walls are exposed to the condenser temperature, and second, to the elimination of exhaust valves and the clearance spaces which they entail.

High Vacuum Effective.

A further gain, however, results from the fact that the large area of the exhaust ports permits the bringing of a high vacuum into effective use on the cylinder. To make the most of this factor, special condensing plant must be employed. Where an adequate water supply is available, and a suitable type of condenser is used, it is possible to maintain an effective vacuum of 28 in. and even 29 in. on the piston. The uniflow type of engine has also mechanical advantages. It is simpler in construction and has fewer parts. The working friction is, consequently, less than with a cross compound engine, and a mechanical efficiency as high as 94 per cent. can be obtained. The costs of attendance, oil, repairs and insurance are correspondingly reduced; and the first cost of building and foundations is much smaller. Because of its moderate speed the engine is particularly suitable for weaving sheds, since it can be coupled direct to the main line shaft without the interposition of ropes, belts or gears. Mr. Ingham places the overall economy of such an engine and drive at from 5 to 7 per cent. higher than that obtainable from a cross compound engine.

The engine has also the same rate of steam consumption per horse-power over a fairly wide range of load, which is important in the case of mills where the load is variable or in new mills where it is necesary to have a margin of power available against future extensions. As to speed regulations, a maximum variation of 1½ per cent. has been obtained in everyday practice. This tained with first-class cross compound engines, but is quite satisfactory.

REPLACING GASOLINE WITH COAL GAS

THE use of coal gas in place of gasoline has received notable impulse in Britain recently, due to the scarcity and expense of gasoline for commercial purposes. In order to obtain definite information, the British Commercial Gas Association carried out extensive experiments which formed the basis of a report by F. W. Goodenough, which has just been published.

It is pointed out that there is no essential difference between a gas engine and a petrol engine. To convert a gas engine for use with petrol, the principal alteration needed is the addition of a carburetor, while the adaptation of gas to a petrol engine simply renders the carburetor superfluous. Petrol possesses the immense advantage of containing a large amount of energy in a small space. Coal gas, on the other hand, being for practical purposes a "perfect gas," not a vapor, conduces to clean pistons and cylinders, absence of troubles due to injector stoppages, and the complete elimination of starting difficulties in cold weather. For equal energy, however, it is very much more bulky than petrol, and herein lies the only real difficulty in connection with its use as a substitute. The gas supplies in different parts of the country not being standardized either in quality or in price, the gas obtained at some places will give a better mileage than that obtained at others; the gas equivalent, however, is unlikely ever to be higher than 300 cubic feet per gallon of petrol, but may be as low as, and even lower than, 250 cubic feet.

Flexible Gas Containers

The method of storing the gas in a flexible, balloon-like holder under a very slight pressure, probably only a few tenths of an inch head (water-gauge) above atmosphere, has several obvious advantages. The holder can be easily and cheaply replenished with gas from any ordinary supply and behaves as its own constant-pressure governor, thus obviating the need for auxiliary governing accessories; it is cheap to install and adds little or no weight to the vehicle, and there is no need for gas-compressing machinery. The practical disadvantages are the fragile nature of the holder and its bulky dimensions, which seem to unfit it for hard work in towns; nevertheless, owing to its simplicity and low cost, the system warrants careful consideration as a war measure.

From the practical engineering point of view, however, the report declares the use of gas compressed into steel cylinders to be far better, though this method must be for the future, owing to the present state of the iron market. At one time there was a considerable weight of opinion in favor of compression to 120 atmospheres (1,800 pounds per square inch), but to this there are several objections, such as the high cost of compression, the care and supervision required in dealing with cylinders stressed to this degree, the liability of the metal to more rapid "fatigue" owing to continual vibration, and the depreciation of the gas by subjection to such a high pressure. Experiments with gas stored at this extreme pressure were found to be impossible owing to the lack of the necessary material and apparatus, but experiments were made on the lines along which ultimate success will probably lie, if gas is at all practicable on a large scale, namely, the use of moderate pressures up to 20 or 25 atmospheres (300 to 375 pounds per square inch.)

There was no opportunity of determining, under present conditions, the effect on the calorific value due to compression to 20 atmospheres, but from observations made seven years ago it was found that the loss due to compression to 300 pounds per square inch was from 3 to 4 per cent., so that if due allowance be made for the difference in constitution of the gas at the present day the effect of compression would be less than 3 per cent. and probably virtually negligible. Compression to only 20 atmospheres would cause the gas to deposit 95 per cent. of its normal water contents, and, as in practice it would have very little opportunity of taking up water on its release from the storage cylinders, it would be used in a virtually dry state. The avoidance in this way of dilution by water vapor would compensate for the loss of calorific value due to deposition of hydrocarbons at 20 to 25 atmospheres' compression.

Result of Experiments

As to the nature of the hydrocarbons thrown down by compression, naphthalene will be precipitated, but observations go to show that there is always a sufficiency of liquid bodies to prevent it from assuming the solid form. These liquid bodies, however, have a tendency to polymerize, and therefore it appears desirable that containers for high-pressure gas should be fitted with drain cocks, and perhaps provision should be made for the occasional use of small hand-operated spraying device to facilitate the outflow of viscid deposits.

While there would certainly be a larger deposit of hydrocarbons at extreme pressure like 120 atmospheres, there would at the same time be greater difficulty in cleaning out the containers. It would probably be necessary to expel the deposited matter by means of heating, which would mean the dismantling of the cylinders—an expensive job. The periodical heating would also in time adversely affect the strength of the cylinders and this seems a weighty reason in addition to those already enumerated against the adoption of pressure higher than 25 atmospheres. Another point is that with 120 atmospheres the reservoirs would be smaller and the deposits greater than at 25 atmospheres, so that the volumetric capacity of the reservoirs would suffer serious diminution unless they were frequently cleaned.

Operating Weights

Figures given for several steel reservoirs show that the weights for 1,000 cubic feet of free gas vary from 1,455 pounds to 1,900 pounds for pressures of 20 to 25 atmospheres, down to 1,080 pounds for 120 atmospheres. The report states that there is reason to believe that after the war the question of weight will be found less formidable than at present, and that the weights quoted for reservoirs will be capable of reduction by 50 per cent. or more, owing to the production of steel of greater tensile strength.

Power Transmission Section

COOLING OF HIGH PRESSURE AIR COMPRESSORS

THE importance of keeping low the temperature within a compressor has already been emphasized. High temperatures are detrimental to satisfactory operation of the machine, and in addition give an increase in the work required. Special attention should be given to cooling arrangements. The best time to effect the cooling is during the actual compression, as this tends to keep the compression low near the isothermal. There are two methods of cooling during compression, namely, jacketing the cylinder and injecting water into the compressor. Regarding the latter, it is necessary to use fresh or distilled water, as any deposit would have harmful results on the cylinder bores, valves, etc.

Jacketing.—This method, although efficacious to a certain point, is only used in a few isolated cases, and the majority of machines are fitted with water jackets, which act in exactly the same way as the jackets on internal combustion engines. In high-speed machines, however, jacketing is of comparatively little value on account of the rate at which heat is generated, and as a result the compression law approximates to the adiabatic. The conditions are sometimes aggravated by a bad arrangement of valves, or thick liner flanges just where the cooling is most wanted, and these points, coupled with bad jacket circulation caused by air locks resulting from faulty design, render the cooling on some machines practically valueless as far as the work done, etc., is concerned. On the other hand, in machines designed with large clearance volumes (the low-pressure cylinder, of course, excepted) the cooling can be considerably improved by using a submerged pipe to conduct the air between the cylinder proper and the valves. This means that there is an increase in the cooling surface, and, moreover, the cooling here can be effected under the best conditions as to conductivity of the walls, etc. Not only is the air cooled during compression, but it also loses heat during re-expansion, so that the incoming air meets with comparatively cool clearance air, which condition assists in keeping low the initial compression temperature, and thereby reducing the maximum cylinder temperature.

Intercoolers.—In practice, however, as is is impossible to deliver the air directly from one stage to the next in a cool condition, it becomes necessary to resort to intercooling. Between the stages the air is passed over a suitable cooling surface, which abstracts the remaining heat resulting from the compression in the lower stage, and the air enters the next stage cylinder in a cool state, the necessity for which has been previously explained. Intercoolers may consist of a simple coiled pipe, or may be of the multitubular type—similar to a surface condenser. The coiled pipe type takes up far more space per square foot of cooling surface than the multitubular variety, unless the construction of the machine permits of the coil being placed in the jacket round the cylinders, in which case a very compact arrangement is obtained at little cost. A point with this arrangement which merits attention is the supporting of the coils. When a compressor is running at full load of, say, 1,500 lb. per square inch, a very decided "thump" can be felt on the discharge pipe with each delivery of air, resulting in excessive vibration of the pipe unless carefully stayed. In time, fracture of the pipe results, and if the coil happens to be carrying a high pressure, the effects may be considerable. Additional protection can be secured by making the coil of thicker gauge pipe, which procedure, within limits, actually improves the cooling for a given bore of tube, on account of the increased external surface.

The construction of tubular intercoolers is along similar lines to that of surface condensers, except that whereas in the latter the tubes are usually secured by ferrules, in the former they are almost invariably expanded at the ends, as the size does not warrant the more elaborate construction. Copper tubes and steel tube plates, which are unusual in condensers, are frequently used in intercoolers, the tubes varying in modern practice from ¼ in. to 1 in. outside diameter. With intercoolers the water is outside and the air flows through the tubes. Multitubular coolers are used for pressures up to about 450 lb. per square inch, and above this the submerged coil type is adopted, as necessitating fewer joints.

Cooling in General.—The cylinders may have jackets cast intergrally—which on account of cleaning difficulties is not to be highly recommended—or separate jackets may be used. The best arrangement is to immerse the whole of the cylinders, valve chests, connecting pipes and intercoolers in a "tank." In other designs there is always present the possibility of air pockets, or the intercoolers taking most of the water and causing the jackets proper to heat, in addition to which the inconvenience of exposed copper pipes at high temperatures is not inconsiderable. In many cases, however, the question of space prohibits the adoption of the "tank" system of cooling, and it is necessary then to jacket connecting pipes and fit valves to regulate the water supply to the various elements. For aftercoolers, a usual method adopted is to have two concentric tubes, the air passing through the central pipe and water flowing in the annulus between them.

Regulation and Control

Perhaps in no branch of mechanical engineering is there more scope for control arrangements for regulating output than with compressor work. The subject is extensive, and only an outline can be given of the several methods whereby the output of a compressor may be altered, the speed being maintained constant. The usual arrangement has for its object the maintenance of a constant delivery pressure, with varying volume output, and consists simply of suitable means for throttling the suction air and thereby altering the volume of air aspired by the machine. The effect of this on the work distribution, temperatures, etc., has already been discussed in the notes on clearance.

Another method of achieving the same object, but which only gives two definite capacities, is to arrange that the stage pressures under normal conditions shall be low, and to provide an auxiliary low-pressure cylinder, so that, when the increased output is desired, this cylinder delivers air as well as the main low-pressure cylinder. A third method is to alter the effective capacities of the various stage cylinders by adding for the time being suitable clearance volume, resulting in less air being dealt with. An advantage of the system is that the correct work distribution may be maintained at the reduced capacity. The above alterations in capacity may be effected by hand or automatically by a system of pneumatic relays controlled by the final delivery pressure.

It is assumed, of course, that the speed remains unaltered, although by changing this it is obvious that regulation can be effected. This method, however, would clearly not be permissible in a Diesel engine compressor.

TRANSMISSION SPEED DATA CHART.

TRANSMISSION SPEED DATA CHART

By J. H. R.

PRACTICAL problems involving the application of arithmetical calculations are often encountered in machine shop work. The solution of many of these apparently perplexing operations is invariably left to the foreman of the department, partly because he is responsible for that particular duty, but more often for the reason that a large number of the men under him do not, or possibly will not, acquire the necessary knowledge to perform the mental tasks that are unquestionably the foundation of the very work they are engaged in. It is a deplorable fact that a large number of workmen have neglected to retain the learning of their earlier days, when their school tasks were more of a mental than a physical character. There are also others that are unconsciously supplied with the potential requirements, but fail to see where they can make practical application of this elementary yet fundamental knowledge.

Calculations for the speeds of shafting, and the diameters of the pulleys by which the speeds are determined, are probably among the most frequent problems met with in general machine shop practice. Work of this character resolves itself down to simple proportion, or the rule of three where the equation of two ratios comprises the basis of operations. For instance, a line shaft running 200 revolutions per minute, is fitted with an 18 inch pulley and it is required to drive a countershaft at a speed of 120 rev. per

min.; what must be the diameter of pulley on the latter shaft? As pulleys derive their motion from the connecting belt it is obvious that the surface speed of coupled pulleys must always be the same (neglecting slippage). However, as the circumferences of pulleys vary directly as their diameters, it is the practice to use the latter in the calculations, therefore, as the speed of the known pulley is equal to $18 \times 3.1416 \times 200$, the diameter of the required pulley will be this value divided by the product of the speed and the constant 3.1416, or $\frac{18 \times 3.1416 \times 200}{129 \times 3.1416} = 30$ inches. It will be noticed that the value 3.1416 is common to both the numerator and the denominator, thus the practice of eliminating this factor.

The accompanying chart illustrates a convenient method of finding the various values of pulleys, shafts and belt speeds in transmission problems. The left hand column represents the diameters of pulleys in inches; the middle column indicates the belt speeds in feet per minute; and the right hand scale denotes the speed of the shaft in revolutions per minute.

To illustrate the operation of the chart we will suppose that the line shaft has a running speed of 180 rev. per min., and is fitted with a 60 inch pulley. applying a scale or fine taut thread from the points on the two outer scales, it will be found that the line intersects the middle column at the graduation between 2800 and 3000—the actual value by calculation being 2827—this being the surface speed of the belt. As the diameter of the driving pulley must necessarily determine the belt speed, it is evident that the coupled pulley will have a similar surface speed. Therefore by using the straight edge and connecting the intersection of the middle line with a certain diameter of pulley (in this case 20 inches), we find the speed of the second shaft to be 540 rev. per min. To compound this drive by using a second set of pulleys we continue as before. Connect the last found value (540 revs.) with the second driving pulley diameter, 30 inches, and through the intersection of the middle scale, connect with the final speed desired (in this particular case 2800 revs. per min.), and we at once find 5¾ inches as the diameter of the second driven pulley.

In the lower left hand corner of the chart are given the necessary data and formulae to solve for the various values. It will be noticed that the product of the speed and the diameter of a pulley on one shaft always equal the product of the speed and diameter of a pulley on another shaft, when the two are belted together. It will also be noted that the diameters are in inverse proportion to their respective speeds, that is, the smaller of a pair of coupled pulleys will always run the faster. The surface speed of the pulley, which is likewise the belt speed, can be found by using the formula, $S = \frac{3.1416\ D\ R}{12} = .2618\ D\ R$.

Example:—To find the belt speed of a drive when the driving pulley is 28 inches in diameter and running at 225 rev. per min., the solution would be $S = .2618\ D\ R = .2618 \times 28 \times 225 = 1649$ feet per minute. In a compound drive, where it is desired to find the final shaft speed and the various pulley diameters are known, also the speed of the driving shaft, the formula:— $F = \frac{R\ D\ D^1\ D^{11}}{r\ r^1\ r^{11}}$ is used. Suppose the line shaft runs at a speed of 160 revs. per min., and the driving pulleys have diameters of 36 inches, 30 inches and 20 inches, with driven pulleys of 24 inches, 18 inches and 6 inches, the resultant speed of the final shaft would be:—

$$F = \frac{R\ D\ D^1\ D^{11}}{r\ r^1\ r^{11}} = \frac{160 \times 36 \times 30 \times 20}{24 \times 18 \times 6} =$$

1333 rev. per min. nearly.

BALL BEARINGS

By C. T.

EVERY specialist whose work and effort lies in more or less narrow grooves is apt to consider that his particular specialty is of universal application. The fallacy of the position is easily realized, and much harm has been done to many good devices by irrational recommendation. The case of ball bearings is a case in point. These are decidedly not applicable in a universal sense, and their limitations are obvious to most engineers. It is impossible to utilize ball bearings in connecting rod ends; ball thrust has been tried for a steamer's thrust block, but has not met with general acceptance. It is doubtful if a ship's tunnel would prove a suitable field. The average practical man would hesitate a long time before prescribing ball bearings for a dusty atmosphere or where adverse conditions as to moisture or fumes exist.

The average ball bearing salesman is an enthusiast, the average engineer a cautious, skeptical person, and to overcome the prejudices of the latter it will need more than a mere statement or anti-frictional proof on the part of the former. The average engineer prefers stable and reliable conditions, or even something which gives limited and recurrent trouble to any alternative whose failure means a total and expensive breakdown. Ball bearings in general are not suitable for shock stress, or for heavy-running load, though for great loads under thrust conditions, such as occur in crane hooks they are admirable. In this last case, however, all the load is carried by the balls, and consequently the stress is evenly distributed.

The success of the ball bearing depends on nearly absolute refinements, sphericity of ball and perfectly hardened and polished races. Quite a small speck of grit can play the mischief, and once there is the slightest abrasion total failure is very speedy. Moreover, the specialist-made article may be wrongly applied in service, and so, through no default of the maker, be unsatisfactory. In no other manufacturing industry is the same perfection of product needed.

As a consequence, in certain locations and for certain purposes where speed and low co-efficient of friction are of the highest importance, ball bearings are the only solution. For universal consumption as a panacea for all bearing ills they have their limitations, and by reason of cost and unsuitability will never become general or replace babbit or gun-metal in a universal sense. In these days, when concurrent efforts to produce machinery producing complicated functions and to simplify mechanism as far as possible, are so greatly intensified, it is necessary to keep in mind both the uses and limitations of those triumphs of skill, the ball bearings. Also to remember that even yet much remains to be said as regards their design and manufacture, as recent discussions before the professional societies have shown.

OILING THE LINESHAFT

By A. L. Loy.

IN passing through a machine shop the writer noticed that about three feet below the main lineshaft was placed a platform about twelve inches wide. The shop was rather long, and this platform, consisting of a plank laid on brackets fastened to the building columns, extended the full length. When oiling the shaft, the oiler could traverse the entire distance without once getting to the floor, doing away entirely with the use of a ladder. The platform also came in handy in putting on or making repairs to belts. Of course, such an arrangement is possible only where the lineshaft follows the building columns.

IN the past nitric acid carboys have been closed by a loose-fitting stopper surrounded by clay or plaster of Paris, all held in place by burlap or similar material. This, says the Chemical Trades Journal, has proved very unsatisfactory, and many cases of leakage, with consequent destruction of property and injury to persons, have resulted, and it is believed that the majority of the fires in nitric acid shipments have their basic cause in defective closure. Experiments to determine practicable methods for the improvement of these conditions have been made by prominent manufacturers of acids, and when recently the situation became especially acute on account of the large increase in acid shipments, the Bureau of Explosives, with full support of the Manufacturing Chemists' Association, decided to require the use of a positive form of closure, consisting of a stopper with gasket held in place by some form of wire fastening. This is now being adopted voluntarily by the nitric acid interests, and will be recommended as a requirement of the regulations in the near future.

Steam And Its Generators

GAS EXPLOSIONS IN BOILER FURNACES.

WHEN certain conditions are fulfilled in a boiler furnace, a gas explosion of greater or less intensity will occur. For every explosion of this kind that causes material damage, there is doubtless a large number that are so unimportant that they entirely escape notice; but the fact that they do occur is well known to all persons who are familiar with the operation of steam boilers. These explosions are common to all types of boilers, and the method of setting the boilers over their furnaces appears to have little to do with the frequency or severity of them. In a general way it may be said, also, that the kind of fuel used is not the determining factor. Explosions of the gases distilled off from coal are frequent, and accidents of the same kind are far from uncommon in connection with the use of oil and natural gas for fuel. Occasionally, too, wood waste or other similarly bulky fuel which is likely to gasify rapidly is known to produce explosive gas. These explosions are likely to continue so long as fuel is burned in confined spaces such as boiler furnaces, as it is practically impossible to eliminate them entirely. It is feasible, however, to minimize the danger from them to a large extent.

Coal Burning Furnaces.

Coal being the most commonly used fuel, it follows that the greater number of explosions occur in coal-burning furnaces. The furnaces of heating apparatus are practically immune from such accidents, however, because the conditions under which they are operated are usually quite different from those that obtain in power-generating equipment, and for the further reason that, except perhaps in installations of large size, it is common to use anthracite for heating purposes, and this produces little gas as compared with bituminous coal. We recall one case, however, in which serious damage was done to a cast-iron sectional heating boiler and to the surrounding property by a gas explosion in the furnace. In this particular instance coke was the fuel used, and the explosion was so violent that the boiler was almost totally demolished, and serious personal injury would certainly have resulted also, if anybody had been in the vicinity at the time.

Gas explosions in coal-burning furnaces are chiefly due to the incomplete combustion of the fuel on the grates and of the gases in the combustion chamber, owing to an insufficient air supply. In the combustion of coal, carbon—its chief constituent — combines with the oxygen of the air which is drawn up through the grates, with the ultimate formation of a considerable quantity of carbon monoxide gas, CO, and this, when sufficiently heated, has a strong affinity for additional oxygen. Under proper operating conditions, and with an adequate supply of air, the carbon monoxide is quietly burned to carbon dioxide CO_2 in the combustion chamber, and the danger of explosion is then past. If the air is not provided in sufficient quantity, however, there will not be enough oxygen to convert the monoxide immediately into carbon dioxide; and when this condition prevails, the unconsumed but inflammable monoxide gas passes along through the furnace, combustion chamber, and tubes, and eventually up the stack still unburned.

If a considerable amount of air is admitted through the fire-doors or elsewhere above the level of the fuel bed in the furnace, the carbon monoxide in the furnace will burn quietly if the proper temperature prevails in the furnace. If, on the other hand, the temperature in the furnace is low and the fuel bed is covered with fresh coal so that immediate ignition of the gas is not assured as the air enters the furnace, then the entering air will mix with the inflammable monoxide gas, and what happens after this depends upon a number of factors. If the mixture so produced is such that the proportion of carbon monoxide to oxygen is greater or less than certain limiting percentages, then no explosion, in the true sense of the word, can occur, even upon the application of flame. There is, however, a certain critical range of proportions that the mixture may have, such that a quite serious explosion may occur if the gas is present in any considerable amount, and is fired in any way. The firing may be accomplished by stirring up the fuel bed on the grates, or by a tongue of flame coming up through black coal by which the incandescent part of the fire has been blanketed or smothered, or in other ways.

If the circulation of gases through the furnace is brisk, there is little or no chance of a gas explosion; but when the circulation has been checked by closing the damper, or throwing on large quantities of fresh coal, or in any other way, pockets of explosive gas may accumulate in the setting, and these may later give rise to an accident.

In the event of a serious explosion, the least that can be expected is that the fire-doors will be blown open and the burning fuel thrown out into the boiler-room, with the possibility of setting fire to the building. In addition, any person who may be in front of the boiler at the time is likely to be severely and perhaps fatally injured. The probability of more extensive property damage is not remote, and the boiler front and setting, and parts of the building, may show the effects of the explosion. In severe cases, too, the shock produced by the gas explosion may cause one or more of the boilers to burst. Many of the "mysterious" explosions that have occurred have very likely been due to such a cause, and in some cases it has been demonstrated that exceedingly serious explosions have been produced in this way.

Precautions Against Explosions.

To prevent such explosions, or to minimize the danger from them, it is important to regulate the air supply in such a way that complete combustion of the fuel and of the gases derived from it will take place when operating conditions are normal, and to assist the combustion or to remove the gases in a safe manner when unusual conditions prevail.

Normally, with a well-designed boiler installation, the draft, either natural or artificial, prevents the accumulation of pockets of explosive gases, but the danger arises when this circulation is checked by banking the fires, or by running them low when only a small amount of steam is required. At such times, therefore, special caution is necessary. Careful preparation of the fires is important, before banking them. Clean the fires and remove the ashes a short time before shutting down the boilers, and then allow the fires to burn up evenly over the entire surface of the grates, seeing that the fuel bed is leveled to an approximately uniform thickness. Next apply the banking fuel, taking care that this is also spread on uniformly and in sufficient quantity.

As a rule, the dampers in the uptakes of boilers are perforated or slotted so that there will be a slight draft through them even when they are in the "fully-closed" position. If such provision is lacking, however, the dampers should be

left partly open, and usually the explosive gases will then pass out through the chimney, because they are somewhat lighter than the air, and are first to feel the influence of the draft. Under certain conditions, these gases may be by-passed to the stack, and if the by-passes are correctly proportioned the loss in boiler efficiency, even under operating conditions, will be inconsequential. A by-pass of this kind is particularly important in connection with a boiler in which the gases between the combustion chamber and the stack follow a downward direction during any part of their travel.

As a further safety measure, the dampers and fire-doors should be opened in the morning before the fires are broken up, so that any gases that may have accumulated during the night will be swept out of the setting

Safety fire-doors have been designed for the protection of the firemen and others against the showers of burning fuel that are sometimes projected from the furnaces by gas explosions. In some types the doors slide in guides, sidewise or vertically, instead of swinging on hinges. Sometimes, too, the doors are hinged so that they swing into the furnace, instead of outwardly into the fire-room; and in other cases ordinary doors are provided with special safety catches. A practical device of some one of these types is recommended for use in cases where gas explosions are common.

Oil or Gas Fuel Furnaces

The likelihood of having gas explosions is especially pronounced when either oil or gas is used for fuel, unless the fireman is an exceedingly careful person. In lighting the fire in such cases, burning cotton waste or a burning torch or some other kind should be placed in the furnace before the fuel-supply valve is opened. In this way the fuel will be ignited at once, and before any explosive vapors or gases can accumulate in the furnace. If a burner should become extinguished (or "snap out"), while the boiler is in operation, because of water in the oil, or on account of temporary stoppage of the fuel supply, or for any other reason the supply valve should be closed at once; and the furnace and all of the gas passages should be ventilated thoroughly before again lighting the fire.

Various special precautions against gas explosions may be required when forced or induced draft is employed, and in such cases the judgment and skill of the engineer in charge may be severely taxed to provide a remedy without sacrificing something of the efficiency of the boiler, because in boilers of ordinary design the maximum efficiency is usually obtained with a comparatively low velocity of the products of combustion, while the prevention of gas explosions depends largely upon maintaining a fairly rapid circulation. A way may usually be found to overcome these difficulties, however, and safety demands that earnest and consistent efforts be made to arrive at a proper solution of the problem.

MOTIVE POWER FOR SMALL USERS

By C. T.

THE question of the best motive power for small users, as determined by the use of steam, gas or electricity, is one that can only be answered by a full knowledge of the circumstances existing in each particular case. In a case which was considered recently, where duplicate power was absolutely necessary, where the user had two engines and two boilers, one of each being always at rest, but ready to be started at a moment's emergency, the question was raised, when one of the engines had worn out, whether another engine should be installed or whether gas or electricity should be requisitioned as the motive power. It was ultimately decided that in this particular case another steam engine should be purchased on account of the large capital outlay that would be involved in converting to electricity, gas being quite out of the question. Later, a consulting engineer, who had been asked for an opinion on this problem, recommended that, as additional plant was put in, each machine should have its own motor, and in the case of replacements the same course should be adopted, and when replacement had reached a certain point the older machine should be scrapped and a dynamo put in as a stand-by in case of failure of the electric supply. The advice proved correct, and it shows the advantage of power users going to the expense of getting expert opinion before deciding on the course to be adopted. It is difficult to lay down a hard-and-fast rule for application in every case, but it is possible for steam plant to be scrapped long before it is worn out, and the resulting saving has been so small that it has meant a capital loss.

DEVELOPMENT OF OXYGEN MANUFACTURE

By J. W. G.

THE use of oxygen in connection with welding processes, carbon removal from engine cylinders, etc., has become such a commonplace matter in the ordinary routine of manufacturing activities that little or no thought is ever given to the processes whereby this now indispensable gas is separated and prepared for use.

The commercial production of oxygen dates from the year 1886, in which year operations were commenced by an English concern to develop a process invented by two Frenchmen, the Brin brothers, their process being based on previous discovery by Boussingault in 1851, that barium monoxide absorbs oxygen from the atmosphere when it is heated to 1,000 deg. F., and gives it up again when the temperature is raised to 1,600 deg. F. This cycle of operations was repeated indefinitely, the barium monoxide remaining unaffected by the alternate heating and cooling.

Despite the lapse of time from the original discovery of the process, many practical difficulties still remained until Brin's Oxygen Co. succeeded in developing the manufacture to such a high degree of perfection, that the barium process maintained its superiority against all efforts to develop other processes of obtaining oxygen on a commercial scale.

The commercial liquefaction of air had meanwhile been developed by Prof. Linde of Munich, in 1895, and from that time on the ultimate eclipse of the barium process became more and more a matter of time. The actual process of obtaining oxygen through liquefying air is a highly specialized proceeding and its success has been very complete, the barium process being entirely discarded, although the possibilities of electrolytic cells are the subject of intense experiment and research by interests allied with electric power supply companies, and developments in this direction are pending.

Despite the decadence of the original process, it is gratifying to know, especially at this time that oxygen production in Germany, France and United States was first put on a commercial basis with barium plants designed and erected by the original Brins' Oxygen Co.

LARGE CHIMNEYS UNDER CONSTRUCTION

WHAT will be the largest chimneys in the world, when completed, are being constructed by the Alphons Custodis Chimney Construction Co. of New York. One of these chimneys, which is being built at Tacoma, Wash., for the Tacoma Smelting Co., has the following general dimensions.: Height above ground, 571 feet; inside diameter at top, 25 feet, and outside diameter at base, 50 feet 2 in. The other chimney, which is being constructed for the Anaconda Copper Co., Anaconda, Mont., will have the following dimensions: Height above ground, 525 feet; inside diameter at top, 60 feet, and outside diameter at base, 86 feet. The chimney at Tacoma when completed will be the tallest in the world, and that at Anaconda the largest in diameter.

The largest diameter chimney in existence at the present time was built in 1908 by the same concern for the Boston & Montana Copper Co., at Great Falls, Mont. It is 506 feet high and 50 feet inside diameter. These chimneys are built of special radial brick; some examples of this construction in Canada may be seen at the Toronto Carpet Mfg. Co., the Municipal Incinerator, Toronto, and the Goodyear Tire & Rubber Co. of Canada, Ltd., New Toronto, Ont.

On the subject of aluminum pistons for internal combustion engines, Joseph Leopold, an American engineer with much experience of this class of work, advocates a plain-sided piston of normal length, with circumferential grooves in the skirt, as distinct from the hour-glass or narrow-waisted type. It has only two rings above the gudgeon pin, the lower one having its groove bevelled and the bevel drilled through to the interior. A third ring is provided at the bottom end of the skirt.

REFRIGERATION DEPARTMENT

RAW WATER ICE AND POWER FOR SAME

By J. B. M.

I AM going to try to present the question of raw water ice manufacture in a few words from the standpoint of my experience and allow each one to judge what best meets his requirements. The first question that arises in the minds of the ice manufacturer are the cost of installation, cost of manufacturing and quality of product.

The cost of installation will depend entirely upon the type of power used to operate, so I am unable to give you any definite figures, but will have to allow each of you who are considering the manufacture of raw water ice to take this matter up and investigate for yourselves, but using either oil engine drive or gas engine drive, your investment will be, roughly, 40 per cent. for a complete plant in excess of the cost of installation of distilled water plants.

From the standpoint of cost of operation, fuel cost is a large factor, and worth serious consideration; in fact, from a standpoint of cost operation, there is no economy in the operation of a raw water plant, except such economy as can be realized from the use of cheaper power than steam, regardless of any claims that may be set up by salesmen, based on my experience. You can use for power on raw water plant, water power, steam power, electric power, oil engines or gas engines, or, in fact, any old power. You are all familiar with steam and electricity, and, of course, where electricity can be obtained at a price ranging from one-half cent to one cent per k.w. hour, it is worth serious consideration, as you can eliminate firemen and install your plant from a standpoint of power, for about 20 per cent. initial cost of what it would cost you to install a gas producer and gas engine. As to steam, if I were located so that it was economical to use steam power, I would operate a distilled water plant, as, in my judgment, you would not be justified in putting the necessary investment in tanks and general equipment for making raw water ice for the sake of the quality, generally speaking.

As to gas producers and gas engines, I believe these have been developed to the point where we can class them as a whole as satisfactory, and the cheapest power obtainable. with the exception of water power. Especially is this true where you have a constant load and can operate continuously. The nearer to continuous operation you have the more economical this class of power is. I have seen a great many in operation of different makes, in different sections of the country. One I recall having seen that was claimed to have been in operation twelve years and still giving good service 24 hours a day. I am interested in three companies, using producer gas engines. One of these plants is operated on bituminous coal, one on anthracite coal, and one on city gas. All of these are giving very satisfactory service and producing ice at a fuel cost of less than fifty per cent. of my usual fuel cost on steam plants. This economy, with coal at $3.50 per ton, will amount to about 40 cents per ton of ice produced, on an average. This saving, however, can be greatly increased if we figure the present market price of coal, and there is still a greater saving to be obtained where one is able to get nearer a continuous operation than I have. On a continuous operation, I have produced as high as 27 tons of ice on one ton of coal.

In addition to operating all auxiliaries, including electric generator, air compressors, etc., the great disadvantage I find is in the fact that you have to carry fires in your producers constantly, regardless of whether you are operating or not, which, of course, with the ordinary ice manufacturer, brings his average fuel cost up pretty heavy, as compared with what it would be provided he had a constant operation, as the consumption of coal, standing, is about 75 per cent. as much as though you were operating, provided you operate your plant at all. If the price of coal continues to soar, or even remains at present high prices. the savings will be much greater and force the more serious consideration of power cheaper than steam.

Gas Engine Experience

I make reference here to gas engines, for what it is worth, as I have had more experience with them than with any other power except steam. One thing I especially want to call your attention to in connection with gas engines, viz., that it is necessary to operate them at a high rate of speed and regardless of the claims of some manufacturers that they can satisfactorily connect direct large size compressors or even small size compressors. I was foolish enough to allow one machinery manufacturer to talk me into installing a 75-ton ice making compressor, direct-connected to a gas engine. This compressor was operated at a speed of 205 r.p.m. and gave me no end of trouble, mainly, in my judgment, for the reason that gas engines are built with three cylinders and vertical compressors with two cylinders, and it is impossible to time the stroke of the three cylinders on the gas engine with the two cylinders on the ammonia compressor.

As a result, with every revolution, there is a certain amount of slack in any coupling that can be installed, so that you continuously break either the coupling, or, if the coupling is strong enough to withstand the continuous pound, then the shafting or something else is going to break. Fortunately, I was covered by sufficient guarantees in my purchase and the machinery manufacturers have taken out this particular compressor and are installing a slow speed machine, to be belt driven and, in view of the fact that I am interested in two other plants and have observed numerous others where belt drive is used, I do not anticipate any further trouble, and my advice is, regardless of what power you use, use comparatively slow speed compressors, especially of large size.

Water Available for Product

Now, as to the product, or raw water ice, this is absolutely dependent upon the kind of water available. If any of you are considering putting in raw water plants, by all means do not spare expense or trouble in absolutely determining what your water will do, before tying yourself up on machinery. Almost any soft water will make satisfactory raw water ice. The softer the water the better. Some hard water can be treated chemically, but this usually requires additional expensive tanks and other apparatus for handling, and even then is very often unsatisfactory. Where the water is good for the purpose, you can, by pumping cores, make beautiful ice, in that it is absolutely tasteless and superior in appearance, to the usual distilled water ice, and equally as pure. I do not believe you can make perfect raw water ice without pumping cores. The refilling of the cores can be done with distilled water, if available, and oftentimes adds a little to the appearance of your ice, and your exhaust from either gas or oil engines can be used for evaporating enough steam to give you distilled water to fill cores if desirable. As to the advisability of this, it all depends upon the quality of your water.

I have observed that there is an inclination on the part of some distilled water ice manufacturers to condemn ice made on raw water plants. This is all right, of course, so long as raw water ice does not come into immediate compe-

*From paper read at joint convention of Eastern Ice Association and Middle States Ice Producers' Exchange.

tition, but if it does you should go slow in your criticism. Understand, I am not especially a raw water man, I am interested in four distilled water plants and three raw water can plants, and if I were going to put in additional plants the type of plant I should install would depend altogether on local conditions. There is no doubt but what you, normally, can manufacture raw water ice for less than distilled. The investment per ton, however, is considerably more, so that by the time you consider interest on the additional investment, and additional depreciation, it would average about the same net cost per ton of ice manufactured with coal at normal prices. This being true, the difference between the two is sifted down to the quality of the product, and, in my opinion, with good soft water, raw water ice has the advantage over the distilled.

PRINCIPLE OF MECHANICAL REFRIGERATION

MECHANICAL refrigeration is based upon the condition of certain gases, which, when put under pressure, becomes like water, provided the heat which is developed during compression is extracted. When this pressure is taken off or reduced and the heat returned, the liquid will return to its former condition, namely, gas. If the heat is not immediately returned, it will remain a liquid at the reduced temperature, until it has absorbed from the surrounding bodies all the heat which it requires to bring it back to its gaseous state. Of all gases, the one best adapted for mechanical refrigeration, and which so far has given the best results, is anhydrous ammonia. The pressure required to turn it into a liquid is not very high, about 175 lbs. to the square inch, and the temperature to which it lowers itself when the pressure is reduced to about 15 lbs. is about 40 deg. Fah. below zero. Anhydrous ammonia, or, in fact, any other volatile gas, is expensive; therefore, it is not allowed to go to waste after it has once done its work, all refrigerating machinery being so constructed that the gas is kept in hermetically sealed pipes, and made to do the work through these over and over again.

To indicate briefly the principle of mechanical refrigeration, there is shown herewith a complete refrigerating plant, in diagram form. In following the direction of the arrows it will be seen that the volatile gas passes through a continuous circular process. It will be noticed that the compressor on one side is connected to a refrigerator, and on the other side to a condenser. In the refrigerator the volatile gas, say, ammonia, is kept under a low pressure of about 15 lbs. per square inch, and in the condenser under a higher pressure of about 175 lbs. The compressor pumps the gas out of the refrigerator and delivers it into the condenser. If we start from the compressor, where the ammonia gas is compressed to the pressure required for its liquefaction, say, 175 lbs. per square inch, the compressed but heated gas is delivered into the condenser, consisting of hermetically sealed pipes. Here the compressed gas gets cooled by means of water surrounding the pipes, and after it has been sufficiently cooled, falls down to the bottom of the coil as a liquid. From here the liquid ammonia is passed through a regulating valve into the refrigerator, also consisting of hermetically sealed pipes.

The regulating valve is required in the first place to allow the pressure to be kept in the condenser; and, secondly, to let only so much liquid ammonia pass into the refrigerator as can properly evaporate when passing through the coils. When passing through the regulating valve, the liquid ammonia is suddenly reduced from the high pressure in the condenser to the lower pressure in the evaporator. As in the short time in which the liquid ammonia passes through the valve it cannot absorb any heat, the liquid ammonia reduces its own temperature down to about 40 deg. Fah. below zero. By letting it, at this low temperature, pass slowly through the refrigerator pipes it is given time to absorb from the surrounding air or brine all the heat it requires for its evaporation, and in return cool same.

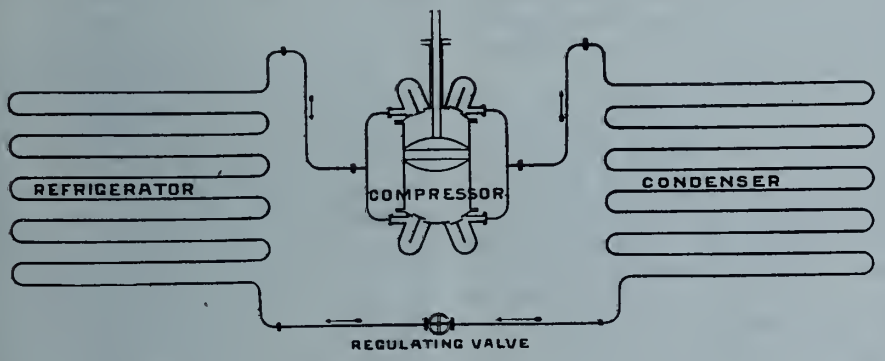

DIAGRAM SHOWING PRINCIPLE O F MECHANICAL REFRIGERATION.

After the liquid ammonia is evaporated—that is, formed into gas, the gas is drawn back by the compressor, is again compressed and delivered into the condenser and liquefied, from whence it again passes into the refrigerator and back to the compressor, and so on indefinitely.

A refrigerator plant, therefore, must always consist of three principal parts: A compressor; a liquefier or condenser; an evaporator or refrigerator.

These three parts cannot work separately, or one without the other, and if one is lacking in construction or capacity, the other two suffer, and cannot make up for the loss. "The strength of a chain is its weakest link" is an axiom that can be well applied to a refrigerating plant, for if one of the three principal parts is weak in construction or design, the other two cannot make it strong, and, therefore, the whole plant is weak. This should always be carefully considered before buying refrigerating machinery, as on the design and construction of the different parts depend the success and efficient working of the refrigerating plant.

THE BEGINNING OF MECHANICAL REFRIGERATION

THE original air refrigerating machine was brought out in 1845 by Dr. Gorrie, of New Orleans, who with Dr. Cullen felt a special need of artificial refrigeration in the aid of his profession. This mechanism had a cylinder in which the air was first compressed. It was passed from this cylinder to a chamber cooled by running water where a pressure of fifteen pounds per square inch above that of the atmosphere was maintained. The air was already cooled partly during compression by the injection of water, the cooling chamber receiving in reality a mixture of air and water. This on passing to another cylinder was expanded down to something like atmospheric pressure. While expanding it was mixed with brine injected into the cylinder, the low temperature of the expanding air communicating itself to the brine. The air on leaving this cylinder was allowed to escape to the atmosphere while the brine, now cooled to 20 deg. F., was conveyed into a tank and applied to ice making.—Edison Monthly.

SEEKING to imitate klingerite, a German packing for steam-pipe joints, French chemists have found a specimen of the material about a sixth of an inch thick to consist of fifteen thicknesses of thin asbestos, says the Chemical Trade Journal. These layers were a compact felting of the best long fibres, mixed with 2 per cent. of flax threads to give strength and pliability, and each side was coated with an agglutinant containing sulphur, designed, it is supposed to increase impermeability and resistance by slow vulcanisation. Analysis showed 80.5 per cent. of asbestos, 2.2 of cellulose (flax), and 17 of rubber and balata, with a small proportion of sulphur.

THE demonstrated advantages of electric motor drive as applied to steel mill-service are rapidly making its use universal in rolling mill work, while as regards reversing mills, substantial evidence of the exceptional superiority of electric drive has been given during the past two years. Less than two years ago there were two electrically-driven reversing mills operating in the United States and one in Canada. In November-1916, there were fifteen mills of this type either in operation or being constructed, whilst in Britain, according to the "British Westinghouse Gazette," there were two.

Electricity and Hydraulics

COMMUTATOR TROUBLES

By A. V. Burr.

ELECTRICAL machines of the commutator type should be given close attention by the operator, especially in regard to the proper operation of the commutator and brushes. It is here that any faults of the machine usually manifest themselves, and any unusual symptoms of impending trouble should be the signal for locating and remedying that trouble as soon as possible, else conditions will soon go from bad to worse and finally result in the total disabling of the machine or necessitate an expensive repair job.

The complicated mechanical structure of the commutator also is a source of inherent weakness, which may develop and hinder it from performing its electrical function in the required manner, with the result that extra duty may be imposed on some parts from others, heating occurs and both commutator and brushes suffer to the deterioration of the machine.

Thus no commutating machine is operating satisfactorily when the following conditions are apparent: (a) sparking at the commutator, (b) noisy operation.

As there are various causes which may be responsible or contribute to the above undesirable conditions, it is hoped that the following arrangement of cause, effect and remedy, may be of assistance to the operator in securing the best possible performance.

In locating the cause of any trouble, mechanical inspection should at first be resorted to and if this fails to reveal the defect, it may be inferred it depends on some faulty electrical condition. Therefore, in ennumerating the various causes they are classified from their mechanical and electrical standpoints and we will first consider those pertaining to sparking.

Mechanical Points

(1) Displaced Commutator Bars: Large commutators with their great number of relatively thin segments and subject to high centrifugal forces, are very apt to undergo some displacement of the bars and a gradual readjustment during their first stages of operation. Symptom: The brushes may be broken or split, and will likely chatter and be abnormally hot. Remedy: Until a permanent condition is reached, the commutator should be tightened, if loose, and trued up from time to time. To do this with small machines, the armature is taken out and turned off in a lathe. With large machines or those of the engine type, mounted on engine shafts, the commutator is either turned off with a lathe tool, or trued off with a grinding tool, with the armature in place in the machine. In the first case a device with a movable tool post is clamped to a stationary part of the machine, the commutator is revolved at the proper cutting speed, and light cuts made across the work. In the second case the commutator revolves at normal speed, while the rotating grinding wheel is moved across the face of the commutator. This form of device is shown in Fig. 1.

(2) Eccentric Condition: The commutator may run out of true due to a bent shaft, spring in shaft from engine thrust or looseness in the bearing. It may also become distorted by being overheated. Symptom: Careful examination shows a rise and fall of the brushes when the commutator turns slowly. The brushes will chatter when running fast. Remedy: If the eccentricity cannot be overcome by remedving these defects turning off or grinding at normal speed should be resorted to.

(3) Mechanical Vibration. This may be evident in machines operated at high speed as turbine driven units, motor generator sets. It denotes either unbalanced rotor or loose commutator, a had belt. or unsteady foundations. Symptom: Considerable vibration is felt when the hand is placed upon the machine and sparking decreases if the vibration is reduced. Remedy: The machine must be re-balanced, either by balancing weights or pouring melted lead into pockets usually provided for that purpose. If a loose commutator is the cause, tighten up the bolts in the clamping rings.

(4) High Mica: This condition most frequently appears in large commutators having a relatively large number of thin commutator bars, where the percentage of mica is high relative to the copper. It shows that the copper is wearing faster than the mica. The use of soft carbon brushes, which though excellent for commutation purposes, are deficient in abrasive material, is usually responsible for high mica. Symptom: The projecting mica, be it ever so slight, can be detected by mechanical inspection. While running, fine pin sparks occur between the faces of the brushes and the commutator, which becomes blackened and burned. Remedy: Special machines are made for the purpose of undercutting the mica to a depth not exceeding 1-16 in. The slot should not be less than 1-32 in. wide so as not to harbor dirt. As a rule the centrifugal forces at this point are sufficient to throw out any ordinary accumulations of dirt.

(5) Dirty Commutator: One objection to undercutting is that material may accumulate in the slots, which with carbon and copper dust will form a conductor between adjacent bars. Dirt and oily dust is also likely to accumulate at the inner and outer corners where the brushes do not touch. Symptom: Such a condition is often the cause for sparking at the end of the commutator flashing and arcing over. Remedy: Make slot inspection and cleaning a part of the regular care of the machine. The end of the commutator should be thoroughly cleaned, and then painted with good insulating varnish, and repainted as often as necessary. The outer and inner corners should be slightly rounded as shown in Fig. II (about 1-16 in. radius).

(6) Pitting of Mica: It is generally considered that the pitting, or eating out, of the mica between the commutator bars, starts from some form of dirt getting in or onto the mica segments. This dirt is more or less of a conductor and the current carried by it, due to the voltage between bars. may sooner or later carbonize the mica so it in turn becomes a conductor. This carbonizing process goes on until holes of considerable size are sometimes produced in the mica. Oil is a common vehicle for transmitting or holding the dirt and care should be taken to see that no oil gets to the commutator by spraying, creepage, etc. Symptom: Burnt spots appear in the mica. Arcing occurs between bars when the current is put on. Remedy: Pick out all the burned particles and then fill the holes up with some form of high grade cement. That used by dentists is very good. Plaster of Paris with sufficient shellac for a bond may also be used. The filling material should be allowed to set thoroughly before the machine is used.

Electrical Points

(1). Wrong Brush Position:—The brushes may not have the proper lead, forward or backward from the neutral position to ensure sparkless commutation. Or the arms carrying the brushes may not be uniformly spaced around the commutator as a result of which some brushes may have the right lead and some the wrong lead. This does not ap-

ply to machines with commutating poles. Sympton:—Bad sparking as the commutator leaves the brush. Remedy:—Shift the brushes or replace the brush arms properly.

(2). Excessive Current.—Sometimes a sudden and very heavy overload such as a short circuit on the line, will cause the current to "bite" into the copper at certain points and leave a condition of roughness. Again a flash over will leave a flat spot on the commutator which will need to be taken out to prevent burning.

Symptom:—Roughness first appears on a few bars at intervals around the commutator. The conditions unless removed tends to get worse and spread around the commutator because it sets up destructive sparking. Remedy:—Smooth the commutator with a fine file or fine sandpaper which should be applied on a block of wood that exactly fits the curvature of the commutator. Be careful to remove any grit particles that remain and never use emery. A block of sandstone used for the purpose is better than sandpaper because of its unyielding nature it shears off the mica at the same rate as it does the copper and leaves the commutator perfectly smooth. The sandpaper or sandstone block is applied while the machine is turning over but without load or voltage. During the smoothing process the brushes should be lifted off the commutator to prevent them from accumulating copper dust.

(3). Brush Conditions.—Anything that causes poor brush contact at one part of the commutator throws an excess current to the other brushes of the same polarity, thereby causing them to be overloaded. Symptom: An overloaded brush may be detected by sparking, by glowing in which spots are heated to incandescence, or by honeycombing in which spots on the face of the brush appear to be eaten out, or by picking up copper where the copper appears to be deposited electrolytically in spots on the face of the brush. Honeycombing often starts at these spots of copper due to the localizing of the current. Remedy: Correct any roughness or eccentricity of the commutator. See that no brushes are clogged in their holders and that they bear with equal pressure on the commutator. The amount of tension to apply must suit the circumstances. Notice whether the commutator is worn in edges causing the brushes to ride up and down as the armature shaft moves back and forth in its bearing. This can be prevented by "staggering" the brushes so that the bearing surfaces in the different sets will overlap. Repair any bad contacts in the shunt connections between the brush and holder. A change in the grade of brush will sometimes improve operation where other things fail.

(4). Armature Condition.—An open circuit in the rotor winding, a bad joint in the winding or a short circuit will cause burning which will start at the bars connected to the defective coils. Symptom: The open circuit will make itself evident by sparking at the brushes. With a bad joint, the sparking may not be so much in evidence, but a gradual blackening of the bars will take place. The short circuited coil will roast out and be liable to damage adjacent coils. Remedy: Repair as soon as possible. In the case of the short circuited coil an emergency repair may be made cutting one of the commutator leads to this coil and attaching a jumper across the commutator bars to which the coil is attached.

(5) Field Conditions: Any conditions which may tend to weaken the field such as high speed or low operating voltage will result in the shifting of the point of commutation with change of load. Symptom: Intermittent sparking with change of load. Remedy: The trouble may be stopped by decreasing the load, shifting the brushes as the load varies, reducing the speed or raising the voltage.

(b) Noisy Operation

This condition indicates a faulty contact between the brushes and commutator through one or any of the following causes: (1) Dry Surface: A dry contact surface will usually cause "squealing" or "chattering" of the brushes. Remedy: It is stopped by using a different grade of brush with better lubricating qualities or simpler still, an occasional application of a small amount of clean oil, except in cases where the mica is undercut when it is not advisable to use oil. Never apply the oil with a cloth or any material having a loose fibre that will cling to the surface and get under the brushes. For this reason cotton waste is a poor material to use. Heavy canvas or a short length of tightly woven cotton hose is good.

(2) Angle of Brushes: The tendency in brushes to chatter may sometimes require the changing the angle of the brush or the relation of the angle to the direction of rotation.

(3) Brushes Loose in Holders: In brush holders of the box type a loose fit may allow the brush to vibrate or chatter. An easy sliding fit is best.

(4) Unevenness of Commutator or Brush Surfaces: Noisy operation is sometimes occasioned by some unevenness of the commutator which strikes the brush a small hammer blow at every revolution. In high speed machines this may be sufficient to split and break the brush.

The face of the brush should have the same curvature as the commutator and be ground to a good fit. Carbon brushes can be fitted perfectly by drawing a strip of sandpaper back and forth between them and the commutator while they are pressing down.

A commutator in normal operation soon acquires a rich bronze glaze or polish and constant vigilance is necessary to maintain it in this state so greatly to be desired.

TUNGSTEN LIGHTING

By B. P. H.

THE subject of illumination is one which concerns everyone in general, but the industrial man in particular. He is dependent to some extent upon artificial lighting during a percentage of the working hours and the quality and effectiveness of the lighting has a direct influence on his results. It is presumed therefore, that a repetition of some elementary rules governing the design and installation of tungsten lighting will be of interest.

The purpose of illumination is to provide a certain needed intensity of light and uniform distribution over an area which is called the working plane.

In any location which it is required to light, the character of the work carried on determines the intensity in foot candles required on the working plane. With this as a working basis every theoretical problem of illumination then resolves itself into a determination of the proper size and arrangement of lamps and reflectors with reference to the working plane, to secure the required intensity and uniformity.

Preliminary Design

With so much excellent data available based on past experience in typical installations, it is a simple matter to choose those empirical values for the different factors such as size of lamp, mounting height and spacing distance, etc., as would seem to fit the circumstances. Thus tables I, II and III present some average co-relations of the different items which have approved themselves in service and which can be accepted as a guide in the design.

It is apparent that for low ceilings the lamps must be fairly close to avoid unsatisfactory shadow effects and therefore the size of lamps should be small and vice versa for high ceilings.

The height and type of ceiling must be considered in the choice of mounting height. As a general rule it is best to mount the lamps within a foot or two of the ceiling as they are then out of the way and less likely to be broken, while the arrangement also makes for freedom from glare and annoying shadows. Besides the light thus transmitted to the ceiling through the reflectors is better diffused and imports a cheerful overhead aspect.

But in cases where the ceiling is broken up by girders or where overhead belting, line shafting or other obstructions will obscure the light it is necessary to lower the mounting and hence use a smaller size lamp over the area affected. Lamps of the same size should always be hung on the same level.

It has been assumed from the study of different installations that the efficiency of a typical shop lighting system based on the average performance of tungsten lights using glass reflectors is around 25%; that is, roughly speaking, one quarter of the total light generated by the lamp is received on the working plane. From this and data supplied by

the lamp manufacturers, it may be deduced that an illumination of one foot candle is given by a lighting intensity of ½ watt per sq. foot and table I has been prepared, using this conversion factor.

TABLE I.

Class of Work—	Foot Candles	Watts per Square ft.
Average manufacturing	3	1.5
Average office	3.5	1.7
Power house	2.0	1.0
Inspection	5.0	2.5
Corridors	1.0	0.5

TABLE II.

Mounting Height, Ft.—	Size of Lamp Watts
7 to 10	40
8 to 12	60
10 to 14	80
12 to 16	100
14 to 20	150
17 to 27	250
25 to 35	400
30 to 40	500

It is obvious that something of a more exact nature than tables II and III is necessary in the practical design, if we are to secure the anticipated intensity of illumination. The following calculations will serve as a check:

Select the size of lamp from table II and the watts per sq. foot from table I. Divide the wattage of the lamp by the watts per sq. foot to give the area of the square in sq. feet of which the lamp is the centre. The square root of this figure will obtain the side of the square in feet or the ideal spacing distance between the lamps, since the lamps are arranged on the square to provide the best distribution of light throughout the location.

W=wattage of lamp. w=watts per sq. foot.

A= area of square. d—ideal spacing distance.

$$d=\sqrt{A}=\sqrt{\frac{W}{w}}$$

Reflectors

As the whole design hinges on the selection of "watts per sq.foot," which in turn, as has been shown, is dependent on the assumed efficiency of the system, it should be remembered that values for the latter change with every condition of ceiling and wall reflection, also with the type of reflector used and the accumulation of dust and dirt on the reflectors and globes. To allow for conditions, a variation up to 15% above and below the given figure for "watts per sq. ft." in table I may be allowed, depending on whether the surroundings are dark or light.

Having fixed on the spacing and mounting conditions of the lamp, the next thing is to choose a suitable reflector from the large variety available. Clear prismatic reflectors are designed for a given ratio of spacing distance to mounting height and may be recommended as having the maximum efficiency and being the easiest to install.

Practical Design

For designing the layout to fit the area and shape of the particular location, some leeway must be allowed in the item of spacing distance so as to avoid any obstacles, such as columns, etc., which might interfere with the placing of the lamp and the shedding of its rays on the working plane. Before hanging the lamps preliminary sketches of plan and elevation should be drawn to scale, showing the location of roof trusses, beams, columns or other obstacles which may affect the installation, also the position of windows, and if previously wired, the present outlets, conduits and switches.

The first row of lamps may then be laid out on the plan, either with reference to the required proximity to the neighboring wall or with a view to effecting economy by using a part of the old system of wiring and outlets. A good practice is to place a row of lamps within 2 ft. 9 in. of the side walls.

TABLE III.

Mounting height, ft.	8	10	12	14	16	18	20	24
Spacing distance, ft.	8	8-10	8-12	8-14	8-16	10-16	10-18	10-20

Different spacing distances can then be tried out until a satisfactory design is completed which evades all obstacles and provides regular spacing, approximating as near as possible the ideal spacing distance. The allowable variation of the spacing distance in the two directions should not exceed 25% of the ideal as shown in composite table IV.

TABLE IV.

Size of Lamp W	Mounting Height	Watts per Sq. ft. w	Ideal Spacing Distance $\sqrt{\frac{W}{w}}$	Min. Spacing Distance	Max. Spacing Distance
Watts	Feet	Watts	Feet	Feet	Feet
		.5	9.0	8.0	10.0
40	7–10	1.5	5.2	4.6	6.0
		2.5	4.0	3.9	4.3
		.5	11.0	9.6	12.9
60	8–12	1.5	6.4	5.6	7.3
		2.5	4.11	4.6	5.6
		.5	12.7	10.6	15.0
80	10–14	1.5	7.4	6.6	8.3
		2.5	5.8	5.0	6.6
		.5	14.5	12.6	16.0
100	12–16	1.5	8.2	6.6	9.6
		2.5	6.4	5.8	7.0
		.5	17.4	15.0	20.0
150	14–20	1.5	10.0	9.0	11.0
		2.5	7.9	7.0	8.6
		.5	22.5	20.0	25.0
250	17–27	1.5	12.11	11.9	14.3
		2.5	10.0	9.0	11.0
		.5	28.2	25.0	31.6
400	25–35	1.5	16.4	15.0	17.9
		2.5	12.7	11.6	13.6
		.5	31.7	28.0	35.6
500	30–40	1.5	18.6	16.6	20.9
		2.5	14.2	12.6	15.0

Specifications

Finally for the convenience of the wiremen make a dimensioned tracing, showing boundary of area, the number of lamps and their position, the grouping of lamps controlled by the same switch and the position of old outlets and switching, if any, which might be utilized to reduce the cost. Flexibility in control also makes for economy by wiring lamps near windows to the same switch, as also lamps extensively used at different times from others.

Estimates

The specifications being completed it is left for the wiremen to pencil in all circuits, to measure up the amount of wire required, to prepare a complete bill of material for the work and to estimate the cost of the installation.

This estimated cost of installation per lamp when compared with the cost in other or similar locations will indicate whether or not the installation cost is excessive. To reduce the cost would require that a lower value of "watts per sq. foot" be chosen in the design and would therefore be at the expense of the resultant illumination intensity.

STEEL CONDUCTORS FOR ELECTRICAL WORK

By D. Street.

GERMANY set the fashion in the use of steel conductors for electrical light work indoors, because, as all the world knows, she requires all the copper she can get hold of for her shells, but now America is following suit because copper is dear; the war has sent up the price to figures that copper mine owners have only hoped for; and now British electrical engineers are also turning their attention in the same direction. Every one is talking of the big bill to be paid after the war and how it behooves everyone else to be saving in every possible way to help pay the bill. After the war it is more than probable that there will be a good deal of inside wiring done in buildings for electric light and power. The metallic filament incandescent lamp enables electric light undertakings to compete very favorably with gas, even in towns where gas is cheap and electricity dear, while the advent of the half watt lamp promises to enable the electric light to sweep the board. In addition, electricity is becoming more and more used in plates of business and private houses for heating and power. Electric cooking is also steadily making its way, as well as the heating of offices and rooms in private houses that are only used occasionally; the latest one price hotels in London have electric fires in all the bedrooms.

All this means more and more small insulated electrical conductors; a great deal of copper. If iron or steel can be substituted for copper for all conductors below a certain gauge, there will be a great saving in copper that can, of course, be used for other purposes; and there should be a considerable saving in cost.

Relative Efficiency

Iron and steel wire of any given gauge, the small gauges for instance used for the bulk of inside work, is only a fraction the cost of copper wire of the same gauge. Iron and steel have electrical resistance six and seven times that of copper; but in a very great number of cases, if the matter is carefully gone into, it will be found that the increased resistance is not of much consequence.

(Continued on page 300.)

Association and Personal

H. A. Harrington, of Toronto, secretary of the Retail Merchants' Association of Canada, has been appointed Assistant Ontario Fuel Controller.

Charles C. Ballantyne, head of the Sherwin-Williams Paint Co., Montreal, and a prominent business man of that city, has been appointed Minister of Public Works in the Dominion Government.

John Dennis has been appointed inspector of stationary and hoisting engineers under the supervision of the Stationary Engineers Board, Department of Public Works for the Province of Ontario. Mr. Dennis who has been serving in the R.N.C.V.R. for the past year was also a member of the C.E.F. until transferred. He served in the British Navy for nine years in the capacity of engine room artificer.

F. Borysewicz has been appointed assistant general manager for Canada, of the Liquid Air Society, with headquarters in Montreal. Before coming to Canada, Mr. Borysewicz was connected with the work of the Society of Japan, having taken a similar position there some years ago, previous to which he had been associated with the head office in Paris, France. In the absence of Mr. Jordan, who is now in France, Mr. Borysewicz is acting general manager.

Lawrence H. Cooney, general manager of the St. Algoma Steel Co. plant and wharves at Sault Ste. Marie, Ont., has resigned. He was for many years in charge of the rolling mill department of the Ohio Works, Carnegie Steel Co., Youngstown, Ohio, before coming to Canada three years ago. He is to be succeeded at the Algoma works by **James Nelson**, who for the past year has been in charge of the duplex department of the Bethlehem Steel Co. at Bethlehem, Pa.

The Electric Furnace Construction Co., Philadelphia announces that **Frank W. Brooke**, who was originally connected with the Gronwall Dixon furnace at Detroit, and latterly as metallurgist for the Ludlam Steel Works and the Ludlam Electric Furnace Co., is joining their staff as director. Mr. Brooke will be responsible for the construction and running of the Greaves-Etchells Furnaces. He will be assisted in the erection and installation by **G. W. Ketter, B.Sc.**, who has installed a great many of the electric furnaces now running and who has just completed the installation of ten furnaces for the British Forgings Co., Toronto.

A. W. McLimont, a leading traction expert, has been appointed general manager of the Winnipeg Electric Railway Co., in succession to Wilford Phillips who has retired. Mr. McLimont is a Canadian and was born in the city of Quebec. Although a young man, he has held a number of important positions, but the work which brought him most prominently in the public eye was the electrification and operation of a considerable proportion of the transportation lines of New York. Mr. McLimont was employed as engineer under the New York Public Service Commission in New York, and became so successful that his services were in demand throughout the United States. Latterly he has been in control of some nine hundred miles of road, constituting the Michigan United Railway System.

EFFECT OF STORAGE ON COAL

A REPORT on the deterioration in the heating value of coal during storage, covering a five-year period, has just been issued by the Bureau of Mines, Department of the Interior, as Bulletin 136, Horace C. Porter and F. K. Ovitz being authors.

The tests show that the amount of deterioration of coal in heating value during storage has commonly been overestimated. Except for the sub-bituminous Wyoming coal, no loss was observed in outdoor weathering greater than 1.2 per cent. in the first year, or 2.1 per cent. in two years.

The loss in heating value is given for New River and Pittsburgh coals during five years' storage in the open air and under water, for Pocahontas during two years' storage in the air, and for Sheridan, Wyoming, coal during two and three-quarters years' storage in the air.

The tests with New River and Pittsburgh coal were made to determine the advantage to be gained by storing coal under water, and particularly under salt water. The results show that storage of New River coal under water effectively prevents deterioration of calorific value and that storage in the air under severe conditions causes only small deterioration, about one per cent. in one year's exposure and about two per cent. in two years. After two years the loss is continuous but slow, reaching 2.5 to 3 per cent. in five years. The deterioration of Pittsburgh coal during one year's open-air storage was practically negligible. During the second, third, fourth and fifth years the deterioration proceeded very slowly and did not reach an amount greater than 1.1 per cent. in five years. The submerged portions suffered no loss measurable by the degree of accuracy of the methods used.

The tests of Pocahontas coal, a semi-bituminous type, were undertaken chiefly to determine the effect of tropical conditions in Panama. They were made on an outdoor pile of 100 tons of run-of-mine coal. During two years' outdoor exposure this coal deteriorated less than one per cent. in heating value.

The Sheridan, Wyoming, sub-bituminous coal, known also as "black lignite," is commonly supposed to deteriorate rapidly in storage, especially by "slacking" or crumbling of the lumps. Under the conditions of the tests this coal lost 3 to 5.5 per cent of its heat value in two and three-fourths years' storage, the greater part of this loss being in the first nine months. In general, the lumps became badly cracked, but retained their form sufficiently to permit ready access of air. However, they were weakened so that they broke up badly on handling. By the use of bins with air tight bottoms and sides and a protecting layer of fine slack on the surface, the deterioration of Sheridan coal in heat value can probably be kept below 3 per cent. in one year, and the physical deterioration can also be largely prevented in the under portions of the pile.

Detailed results and a full account of the tests and analytical data are given in the bulletin, which may be obtained free of charge by addressing the Director of the Bureau of Mines. Washington, D.C.

ACCIDENT PREVENTION

CONSERVATION of life and energy has probably never before been so deeply impressed upon our minds as now. The need of preserving and protecting humanity from the risks of permanent or temporary disablement, arising from industrial activity, has been much emphasized by the knowledge that the past three years has shorn us of much of that man power which is so indispensable to our national development in the arts, crafts and manufactures. What may tend to increase the possibilities of accident, and likewise the responsibilities of the employer and the employed, is the advent of woman labor into the ranks of metal-working plant operators. While the likelihood of accident may be no greater in one case or the other—the female than the male, the fact that the so-called weaker sex must inevitably take a prominent part in post-war development, should be a stimulus to those concerned, to eliminate, or at least constrict the opportunities for injury that have ever been incidental to most phases of manufacture.

While safe-guarding methods and devices are deserving of just commendation they should never be wholly relied upon as an infallible proof of non-liability to injury. No proposed or adopted method of operating or guarding machine mechanisms should be termed fool-proof, even though it has been amply demonstrated that it is practically impossible to tamper with or destroy its intended purpose. The mere statement that a thing is fool-proof implies that it is proof against a fool's meddling, and any fair-minded person would or should resent the implication. It is invariably within the power of the workman to "make" or "mar" any new innovation—providing its effectiveness is being tried for the first time.

It does not pay to "force" protection on factory employees, but it does pay to have them realize the many advantages that are to be derived by adapting themselves to the changed conditions. Some men unfortunately become easily prejudiced, and will for a time do all in their power to deter rather than assist such methods as are advanced for their own welfare and protection. No safety or protective device can be entirely successful without the absolute co-operation of the employees it is intended to serve. If a safety method has any outstanding advantages —and few have not a fair proportion, it should be the duty of the workman to adapt himself as rapidly as possible to the conditions which it imposes, because eventually he will be the chief beneficiary.

LABOR AFTER THE WAR

THERE can be no doubt but that the greatest of after-war problems will be the relations between capital and labor. Men are now being paid wages for munitions and other war-time work which has raised the level of the market to previously unheard of levels. True much of the increased return has been absorbed by the higher cost of living, but in the period after the war, when munitions work stops—when the nations now spending so recklessly start to retrench—the present returns for labor cannot be expected to last. The crux of the situation will be that industrial wages will decline more rapidly than will the cost of living and the civilian individual will then feel the pinch of war conditions, which, generally speaking, he has been far from doing up to the present time.

When the demand for munitions ceases and there is still a shortage in the world food supply, Canada should take her place in the sun to a greater extent than ever as a producer of foodstuffs. For a time at least, especially with the return of the troops, the movement of population promises to be from the urban centres to the rural districts, just as it was the opposite for months after war industrial activity commenced, and not a little evidence is already forthcoming that a "back to the land" movement of fair proportions is gaining momentum and popularity.

The Operators' Point of View

DOES A PISTON STOP AT REVERSAL?

By W. F. Schaphorst, M.E.

R. W. MILLER'S query in your issue of Oct. 4, inspires me to write my convictions pertaining to this question which has been the cause of much "argufication" from time to time.

Yes, a piston stops at reversal. That is, at each end of the stroke of the piston its velocity is zero, and when the velocity of a thing is zero we generally conclude that the thing has "stopped." Mr. Miller states that to stop means to produce a "state of rest." I do not like to use the word "rest" in connection with a piston, because it often signifies sleep, repose, death, and such other items that have comparatively long duration. A piston doesn't rest, therefore, because the period of reversal is infinitesimal. I cannot state "how long" a piston stops, in answer to Mr. Miller's query, nor can anybody else. All I know is that as the piston approaches the end of its stroke, its velocity decreases gradually, and when the end of the stroke is reached, the velocity is zero. At the beginning of the return stroke, then, the velocity is zero from whence it accelerates again to a maximum.

Motion, you know, is only relative anyway. That point has been threshed out very carefully in text books on kinematics, physics, etc. I am pretty sure that all authorities agree that a piston stops at reversal. If it didn't stop, how could it ever start moving in an opposite direction, and all in the same straight line? In a flywheel the particles in the rim constantly change in velocity, but not in speed. Quoting Prof. Goodman: "The velocity of a body may be changed by altering the speed with which it is moving, or by altering the direction in which it is moving. It does not follow that if the speed of a body be uniform, the velocity will be also. The idea of velocity embodies direction of motion, that of speed does not."

We can, therefore, conclude that there is a considerable difference in definitions of words that we commonly regard as synonyms, and in that event "rest" may mean a period of anything from a second to a day, or thereabouts.

As for the argument, "If the piston stopped even for an infinitesimally small fraction of a second, would not the flyhweel to which it is connected stop also?" the piston is no more connected to the flywheel than is the base of the engine. There are several pins connecting the piston with the flywheel, whereas there is but one pin between the base and flywheel. Surely the base is at actual "rest" all of the time.

There are several other instances in which we have "stopping and moving" motion as in the automobile or wagon or carriage tire. A given point in the periphery of the tire moves with variable speed from zero to twice the velocity of the car. When the point is in contact with the road it does not move at all. It stops. Its velocity is zero. As for the duration of the stop—nobody can answer that any more accurately than can Mr. Miller's question be answered.

This takes me to a pet idea of mine pertaining to the question, "Does light stop at reversal?" That's a question that isn't so easily answered, because light, you know, travels at a velocity that is fairly uniform through the air, through a vacuum through glass through water, etc. Now, when light strikes a mirror perpendicularly and is reversed in direction, does it stop? There is no deceleration or acceleration. The writer knows of no reason why there should be a change in velocity, because light has no mass or weight, and therefore concludes that there is no changed velocity. In that case, therefore, the inference must be reached that there is no stopping for there can be no zero velocity when the thing or phenomena or whatever it is is in constant motion.

In comparison the piston problem is easy. There is no question but that the piston stops. The best way in which to oil a piston rod is to oil it at the end of its stroke—when it isn't moving. An automobile tire, you see, catches the mud in a muddy road when its velocity is zero and flings it off soon when high centrifugal force develops. The same is true when you or I run through mud. Mud clings to our shoes when they are in contact and aren't moving at all, but is often thrown off again before the same shoe again strikes or touches the ground.

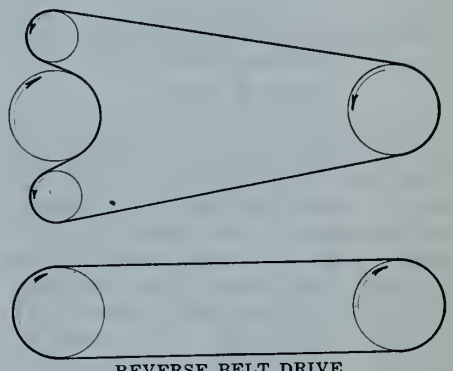
These analogies may seem crude, but in the mind of the writer they are proofs that such objects as pistons, automobile wheels, shoes, etc., all stop at one time or other at periodic intervals.

As for the last paragraph: "To controvert the theory that the flywheel stops, we find in the definition quoted that the point executing the harmonic motion must move with uniform velocity. How can the flywheel stop twice in one revolution, and yet have any point in its circumference move with uniform velocity? —the motion of the piston is just as continuous as the flywheel." This is answered by the quotation above from Prof. Goodman's splendid work, "Mechanics Applied to Engineering." The velocity of a point in a flywheel rim "in a given direction" becomes zero once each revolution. The speed of the flywheel, aside from the fluctuations due to variable load, is constant.

A REVERSE BELT DRIVE

By A. L. Loy

IN a crushed stone plant which the writer recently visited the reverse belt drive for the main crusher was obtained in the manner shown in the drawing rather than by crossing the belt as is the usual practice. Those in charge of the plant were unable to explain the advantages obtained by this design but claimed that it had given perfect satisfaction. Certainly its efficiency would not be as great as the crossed belt due to the friction loss occasioned by the two idlers and the reverse bend would be harder upon the material of the belt. Of course, it is possible to secure a



REVERSE BELT DRIVE.

greater arc on contact by the proper location of the two idlers and this may have been the deciding factor.

INVESTIGATING DEFECTIVE MAGNETO

By J. E. McCormack.

A gasoline engine was equipped with a rotary magneto and with batteries also. The idea was to start on the batteries and switch onto the magneto when speed was up, but as the engine failed to operate on the magneto (in fact the magneto

was supposed to be of no use) the batteries were used entirely for some months. One day I removed the magneto, coil spark plug and connecting wires and placed the magneto on the stand of an old sewing machine from which the head had been removed. I removed the governor pulley from the magneto and bored out an empty (sewing thread) spool to fit the arbor, then used this for a pulley and a grip strap for a belt, I ran the magneto up to approximate speed by pedaling and kept it going and kept adjusting the vibrator on the coil until I got some buzz, and then found that a half turn of the screw either way would stop the buzz. This shows the fineness of the adjustment necessary in that case. The proper point thus located was 3 or 4 turns from where it had been set for use on the batteries. With the new adjustment of the vibrator it was possible to start on the batteries and then run on the magneto, thus greatly saving the said batteries. With the magneto connected up on the engine it had been practically impossible to adjust the vibrator to it, because the engine would not hold up speed sufficiently long, but now with the vibrator set for the magneto, the batteries will work with the same adjustment and it is O.K.

No fastening was required to hold the magneto on the sewing machine stand for testing. Its weight was sufficient to hold it steady and in place. During the testing, I had the ground connection bound to the outer nut of the sparkplug, and the secondary attached to the end of the plug in the ordinary way. This completed the circuit the same as though the spark plug had been screwed into place on the engine and the ground wire attached to the engine frame in the customary manner.

PRACTICAL OBSERVATIONS ON LUBRICATION

By D. O. Barrett

IT is surprising that in the design of up-to-date heavy-duty machine tools how much time and attention have been devoted to certain features of construction and how little to other seemingly unimportant parts but which become quite prominent when trouble occurs as it generally does. One particular place where the above is applicable is in connection with the countershafts usually supplied with all machine tools. On some heavy-duty lathes, in particular, built by manufacturers whose reputation tells the story of their success, countershafts are sent out which are constructed no more rigidly than those of five or ten years ago. We still find light shafting and hangers with long spans between bearings and with light clutches which are continually slipping and will not stand up to the regular work for which the machine is designed.

One source of continual trouble is the lubrication of the loose pulleys or the main driving pulley, in case a clutch is provided. These pulleys have, in most cases, a hole drilled through the hub into which a small quantity of oil may be poured but when the pulley starts to revolve centrifugal force will cause the oil to be thrown out. This applies equally well to the average drill press, which is provided with tight and loose pulleys.

In starting operations in a shop equipped throughout with new machine tools, trouble was experienced from these loose pulleys galling on the shaft due to insufficient lubrication. After loosening up several of these only to have the same thing occur again in a short time,

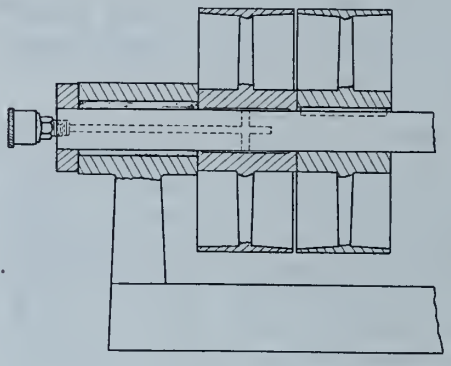


FIG. 1.

the remedy as shown in Fig. 1, was decided upon after which no further trouble was experienced. The shafts were removed and a hole deep enough to reach to the center of the loose pulley put in, with a hand feed grease cup at the end. At the center of the pulley a hole was drilled entirely through the shaft and a couple of extra deep grooves were cut in the pulley bore. The grease could thus be positively forced where most needed. Another advantage was that the oiler could tighten up the cup while the driving belt was on the loose pulley. This method gave such entire satisfaction that all new countershafts and drill presses were equipped accordingly.

Another case where the same method was used to good advantage was in a heavy-duty lathe which had been operated but a few days when the back gears galled on the eccentric shaft. This was removed and drilled out as in Fig. 1 with

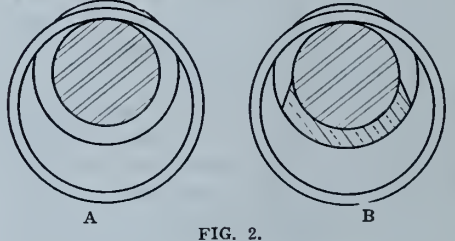

FIG. 2.

a grease cup at the end of the eccentric shaft and no further trouble was experienced.

The countershaft bearing on one of the larger boring mills was continually heating even though supplied with an excess of oil which would seem to be used effectively as the bearing was provided with a ring oiler. Upon investigation it was found that there were two separate bushings in the bearing with the oiling ring running between them as at A, Fig. 2. The oil was thus merely carried around the shaft between the bushings, very little running along the shaft and getting into the bushings. Had the bushing been made in one piece and then milled out at the top, for the ring as at B, the trouble would never have occurred as the edge of the bushing would have caught the oil, forcing it to travel along the shaft. Not having the material to make such a bushing the oiling ring was removed and the space filled with grease and a hand feed cup supplied. Little occurrences like these, while small matters in themselves, nevertheless cause great inconvenience and serve to ruin a reputation which might have been built up on the quality of the machine in general.

In connection with stationary gas engine work, the usual method of lubricating the cam rollers is shown at A, Fig. 3. These rollers are of either tool steel or machine steel case-hardened, and are made rather a loose fit on the hardened steel pin. They are generally made a fairly close fit in the slot which is milled in the end of the push rod which is of square cold drawn steel. A hole is drilled radially through the hole for oil but if the hole should happen to be in any other position than vertical and the roller is against the cam, the average operator does not take the trouble to turn the roller but contents him-

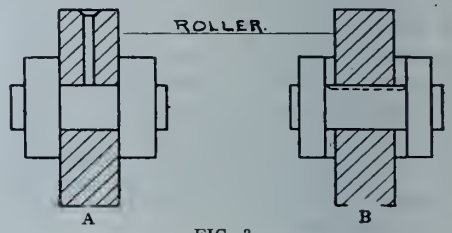

FIG. 3.

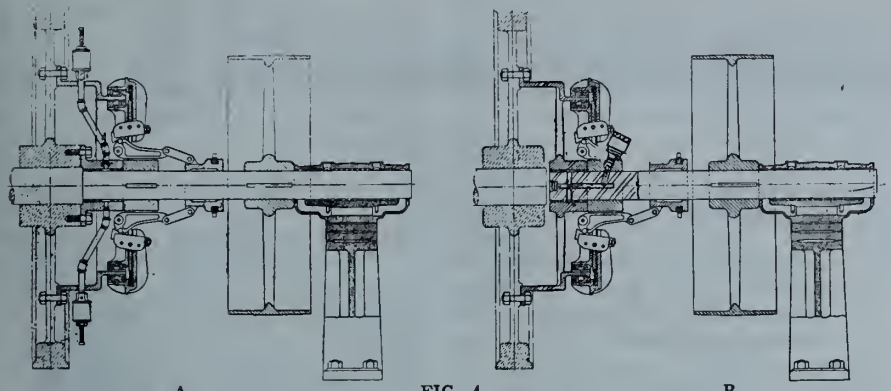
self with pouring a little oil on the side. Should the hole be filled with oil, as soon as the engine is started the centrifugal force will immediately throw it out so that in any case, the method is a failure.

A much better plan is shown at B where the slot is somewhat wider than the roller and the pin is provided with an oil groove for the full width of the slot. Oil applied at either side of the roller will at least fill the groove and cover that part of the pin which is exposed and as soon as the engine is started the roller will travel from side to side spreading the oil effectively over the pin. Oil may, of course, be equally as well applied while the roller is turning.

The usual method of lubrication for clutches and cut-off couplings attached to gas oil engines is shown at A, Fig. 4. The friction ring is bolted directly to the flywheel and the bearing for the shaft carrying the driving pulley is bolted to the wheel or cast integral with the ring. The gripping mechanism is keyed to the extended shaft. In this way the shoes remain stationary and adjustments may be made on the friction

surfaces by merely throwing out the clutch. Self-feeding grease cups are attached to the ring with pipes leading to the bearing. The cups can, of course, be filled only when the engine is shut down and no attention whatever can be given them after the engine is in operation no matter how many times the clutch may be thrown out, with the extended shaft stationary. Again, this style of cup is not very reliable in its operation since the spring operated piston in the cup may not be able to force the lubricant through the long pipe, especially in cold weather.



A FIG. 4. B

At B is shown a method which has proved far more satisfactory and costs little, if any more, to install. The shaft is drilled from the end and then plugged, the hole being deep enough to reach back to the member carrying the shoes. A hole is drilled through the shaft at the center of the bearing and another hole is drilled into the shaft to meet the center hole and corresponding to the grease cup which is carried in the hub of the mechanism. By throwing out the clutch and allowing the engine to run, the cup may be screwed down at any time thus insuring an ample supply of lubricant. Of course, it is necessary that the part carrying the grease cup maintain its exact position with relation to the shaft and this may be accomplished by drilling a shallow hole in the shaft for a set screw which is usually provided in the casting. Hand feed cups are the best for this arrangement as the grease may be positively forced where needed.

SETTING VALVES OF BROWN ENGINE

IN reply to inquiry by R. R. Lambert regarding rules for setting valves of a Brown engine, the following instructions are submitted:—

Steam Spindles

Before setting the valves to time with the crank see that the steam spindles are so adjusted that the valves have the proper lap and the steels on the latch and the lifter have the proper clearance. When the dashpot pistons are resting on the bottoms of the pots and the lifter is at the bottom of its stroke, there should be 1/16 in. clearance between the steels on the latch and the lifter and the lap of the valve should be 3/16 in.

Governor

Next look at the governor. The travel of the governor is usually 5/16 in., but should not exceed ⅜ in. When the governor balls are at their lowest position, the steam valves should trip. When the valve is opened full port and when in their highest position, the valves should trip just when the port is opening. Having adjusted the spindles and governor, the next thing is to set the valves to time with the crank. For the steam valves put the engine on the dead centre and give the valves about 1/16 in. lead. For the exhaust valves set to close at 1/10 of the stroke from the end, being careful to take into consideration the hand to which the engine is running, i.e., be sure that the exhaust valve is set to close at 1/10 of the stroke from the end to which the piston is moving.

STRAIGHTENING SHAFTS

THE straightening of shafts in the lathe is, like many another job, when one knows how to do it, quite a simple one. A knowledge of what is required, and a fair modicum of patience are desiderata and indispensable. Given a shaft, say 2½ in. in diameter, straight from the drawing mills, such a shaft being all that may be desired as regards size and soundness, but with a slight bend, and perhaps two, in its length, such bends precluding its use as a shaft, and fit to run in ordinary journals or in ball bearings. The first thing to do is to chuck one end, run the other in the steady and centre that end with a large centre drill. Then the other end, previously held in the chuck is held in the steady rest and faced and centred. The shaft is then provided with a pair of suitable half clips—it must not be gripped in the chuck—or a suitable driver and the lathe started. Bends in the shaft may be easily discerned, and a rough judgment made as to the size of the "job."

Preliminary Inspection

Notice having been taken as to the extent of the bends, it is as well then to let the centre of the shaft run freely in a steady. The acquisition and use of the steady at this stage, and in the centre of the length of the shaft is simply for the purpose of eliminating an accession of spring which would accrue, as a result of out of balance, were the lathe to be run at a considerable speed. It is quite possible, however, that the worst of the bend may be situated just about in the middle of the shaft. If such be the case, another and more suitable position must be found, i.e., if there be one. If there is no part of the shaft found to run, even approximately true, or in other words, sufficiently true to run in the steady, then it is a case of running the lathe slowly round, so that there is no "swing" as the shaft is rotated, and to choose a part to set true first. When such is done, the steady should be applied and attention given to the straightening of the parts on each side of the steady. It should be observed, however, that there is no royal road to the art of straightening shafts any more than there is to the art of flattening a circular saw, or a large steel plate. An expert at either is able to do with a few blows more than a novice can do in an hour, if at all.

Theory of Drawing

As with circular saw or steel plate flattening a "drawing" of the shorter parts is the essential, and the man who knows how to do this well may become an expert on the straightening of shafts. But we may hear the novice exclaim when his patience has been exhausted towards the removal of recalcitrant bends, "when I get this bend out another comes in." Just so, and this will be the case generally, until by judicious drawing the bends become reduced in extent, and the shaft becomes approximately, or, as it is sometimes called, commercially straight. It may be said that the method of drawing—with the aid of copper pad—flogging hammer and steel lever,—the old-fashioned way—is far more preferable, and a more direct remedy for bent shafts than any crowbar; and for this reason: If the shaft has become bent in transit, or by any other means, the convex side had become long by stretching—and common sense will support the idea that to bring the shaft back to an approximate normal, the concave side should be equally stretched. That may be accomplished with the orthodox accessories, copper pad, flogging hammer and steel bar—as a lever—and by no means excluding a good heavy laborer for the bar, a useful man for the hammer and a skilful man to hold the copper pad and direct operations. Such a man, where many shafts are required to be dealt with, is worth high pay, though difficult to discover.

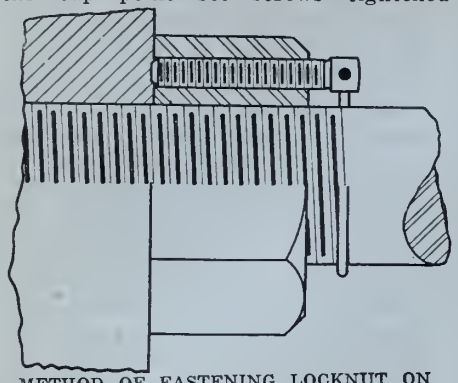
FASTENING SCREWS AND NUTS

By A. L. Loy.

CONSIDERABLE trouble had been experienced with the nuts on the piston rods of gas engines working loose. These nuts were used as lock nuts on the rod where it entered the crosshead. Tightening up the nut draws the threads on the rod to the back of those in the head, so that the pressure of the explosions comes directly on the nut. Should the nut become loosened only slightly, the small movement of the rod in the head will soon work the nut back, and either cause the piston to unscrew or, as sometimes happens, the piston rod is forced through

the crosshead, tearing out the threads.

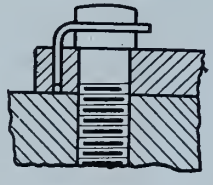
The nuts were drilled and tapped and the cup point set screws tightened



METHOD OF FASTENING LOCKNUT ON BACK OF CROSSHEAD.

against the crosshead after the main nut was tightly drawn up. Holes were drilled through the head of the cap screw and a wire was run through and then wrapped around the rod and the ends fastened together. Since the screw would cut into the metal of the crosshead a certain amount, it would have to back out this amount before the main nut could move and the wire very effectively insured that these parts would remain tight.

A wire may also be used very satisfactorily in the locking of cap screws, as shown in the cut. Holes are drilled through the heads of the screws, and also down into the piece being held by the screw, as close to the screw as convenient. The wire is pushed down into the hole and then pulled through the



LOCKING CAP SCREW WITH WIRE.

head of the screw and cut off. It is immaterial whether the holes line up, as the wire will simply be bent to correspond and cannot come out unless deliberately removed.

A HANDY SAFETY VALVE CHART

By N. G. Near

A FORMULA which I believe is worthy of working into chart form is presented herewith. This is the formula:

$$A = \frac{0.2074\ W\ G}{P}$$

Where A=the area of the safety valve in square inches;

P=the absolute pressure in pounds per square inch;

W=pounds of water evaporated per square foot of grate surface per hour;

G=the grate area in square feet.

To use the chart simply lay a straight edge across the chart twice as shown by means of the dotted lines drawn across this chart and the area is immediately found in column C without doing any pencil or mental figuring at all.

First connect the evaporation per sq. ft. of grate surface per hour (column A) with the grate area (column D) and locate the intersection with column B. Then run a line through the absolute pressure (also in column A) and the intersection which has already been located and the intersection of this line with column C gives the area.

For example, what area of safety valve is required where 60 pounds of steam are evaporated per square foot of grate per hour, where the grate area is 40 square feet, and where the steam pressure is 150 pounds absolute?

The dotted lines show how this particular problem is solved. Connect the 60 (column A) with the 40 (column D) and locate the point where the line cuts column B. Then run a line through this point and the 150 (column A) and an extension of this line cuts column C at the point 3.3. The area of the safety valve should therefore be at least 3.3 square inches.

I believe this method of making double use of column A will interest readers. It serves both for the pressure and the evaporation. The first line connecting the 60 and 40 represents a multiplication as is evident by inspection of the formula. The second line performs the division.

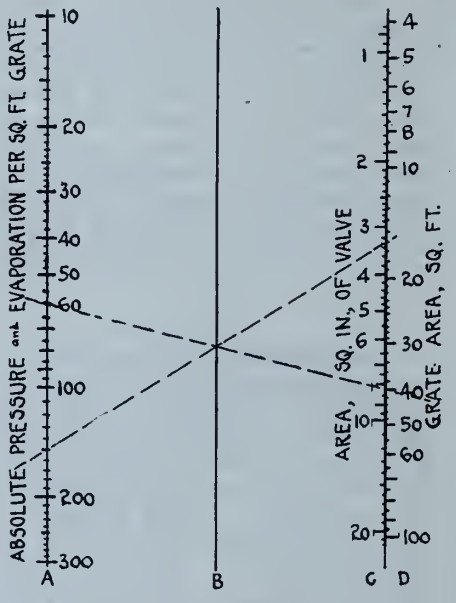


CHART FOR ASCERTAINING SAFETY VALVE RATIOS.

STEEL CONDUCTORS FOR ELECTRICAL WORK

(Continued from page 294.)

The smaller currents required for the metallic filament and half watt lamps allow of distributing conductors of very much higher resistance being employed with the same result at the lamps.

According to the rules issued by the Institution of Electrical Engineers, a total drop of three volts only is allowed, practically inside a building; but a drop of three volts with a certain number of the old carbon filament lamps, taking anywhere up to four watts per candle, is a very different matter from a similar drop with either the metallic filament lamp or the half watt lamp. Merely substituting half watt lamps for carbon filament lamps, where this is practicable, should enable the resistance of the distributing conductor to be increased by at least the difference between the resistance of copper and steel. And this is not all; by the rules of the Institution of Electrical Engineers, no copper conductor is allowed to be employed for work of the kind mentioned of a smaller gauge than No. 18 S.W.G. The reason for this is a purely mechanical one. The passage of an electric current through any conductor tends to make it brittle, particularly at the points where connections are made to terminal screws and at joints; with the result that if the wires employed are allowed to be too small there is a strong tendency for them to be continually breaking at those joints. When joints are made also, as is well known, it is difficult to leave the metal conductor on each side of the joint in the same condition as before the joint was made; there is an increasing tendency to brittleness. Soft steel wire, such as could easily be drawn, would have a very much higher tensile strength than coper wire of the same gauge; and if properly drawn and properly handled should be very much stronger in every way; in fact, so far as mechanical strength is concerned, it should be quite safe to employ soft steel wire of No. 20, and even smaller gauges. The soft steel wire should stand the handling of careless wiremen very much better than copper wire.

Manufacturers of insulated wires would have to tackle the problem of insulating the iron wires very carefully, but there is no reason to suppose that there would be any difficulty about the matter.

Possible Hysteresis Loss

One objection to the use of iron or steel wire is the possible loss that may arise from hysteresis in the wires themselves. It will be remembered that when a current of electricity passes through a conductor it creates a mannetic field around the conductor; and every magnetisable substance meeting the lines of force thrown out from the conductor, responds to them. As the great bulk of electric lighting is now done by the aid of alternating currents, this means that each of the wires forming a pair of conductors, if they were of iron or steel, would be magnetized alternately fifty times a second, or whatever their periodicity might be; and there would be a certain consumption of energy in accomplishing this.

For the small conductors employed for indoor work the loss due to this would be very small; it would be merely an addition to the loss due to the power factor of the whole system, and not a great addition. It is found of advantage to employ alternating currents for distribution. for light, heat and power, notwithstanding the undoubted losses due to the power factor, even under the most favorable conditions, and the small aditional charge due to the employment of iron or steel wires for indoor work would be really inappreciable.

Operators' Instruction Course

REFRIGERATION QUESTIONS AND ANSWERS

Question.—On what principle does a refrigerating machine operate?

Answer.—You compress by means of external force a gas or vapor and extract its heat to diminish its volume. By causing the compressed gas or vapor to expand you lower its temperature. Heat is again absorbed by the gas or vapor, and the latter resumes its original condition, constituting the refrigerating effect of the arrangement.

* * *

Question.—On what does the efficiency of a refrigerating machine depend

Answer.—The efficiency depends on the difference between extremes of temperature.

* * *

Question.—On what does the useful effect of a refrigerating machine depend?

Answer.—It depends upon the ratio between the heat units eliminated and the work expended in compressing and expanding. This result is independent of the nature of the body employed.

* * *

Question.—What would be the amount of heat absorbed per hour by a nest of 1-inch pipe 24 feet long and consisting of 32 pipes? The temperature difference between the brine in the pipe and the freezing room is 20 degs. F., and there are 30 4-inch open return bends.

Answer.—A return bend with openings at 4-inch centres has approximate surface area of 50 sq. inches. Area of 30 bends $= \frac{50 \times 30}{144} = 10.4$ sq. ft. Actual length of pipes = 23 ft. 4 in. Circumference of 1 pipe $= 1.3 \times 3.1416 = 4.084$ inches.

Surface area of pipes $= \frac{280}{12} \times \frac{4.084}{12} \times 32 = 254.115$ sq. ft.

Total surface = 254.115+10.4=264.515 sq. feet.

The coefficient of radiation or absorption for clean iron pipe is .566, which means that .566 B.t.u. of heat will be absorbed for every square foot of surface per hour per degree F. difference in temperature.

The amount of heat absorbed is, therefore, $264.515 \times 20 \times .566 = 2994.31$ B.t.u.

Question.—How many British thermal units would be required to melt one ton of ice at 10 deg. F.?

Answer.—The latent heat of fusion for ice is 144 B.t.u. per pound but, in refrigeration calculations, 142.2 is generally used. The specific heat of ice is 0.504. The heat required to raise 1 ton of ice from 10 degrees to 32 degrees (the melting point) is $(32-10) \times .504 \times 2000$ or $22 \times 2000 \times .504 = 22{,}176$ B.t.u.

The heat required to melt 2,000 pounds of ice at 32 deg. would be $2000 \times 142.2 = 284{,}400$ B.t.u. Total heat required then is $22{,}176 + 284{,}400 = 306{,}576$ B.t.u.

or the equivalent of about $\frac{306{,}576}{10{,}000} = 30.65$ pounds of coal burned under a good boiler.

* * *

Question.—How can the "cooling effect" produced by a refrigeration machine be calculated?

Answer.—There are two general methods of accomplishing this: (1) By its effect on brine or other medium. The quantity of brine, its specific heat, the temperatures through which it is cooled and the time required all determined by observation. From these the number of tons of ice that could be melted per 24 hours can be calculated.

(2) By the amount of ammonia evaporated and passed through the system, the back pressures and compression pressures being known. The cooling effect of the evaporation of the ammonia under these conditions can be calculated and converted to tons per day.

* * *

Question.—The total output of a refrigerating plant is taken up by calcium chloride brine which is circulated by an 8×10 double acting brine pump making 104 strokes per minute. The temperature of the brine leaving the tank is 10 deg. F., and that of the returning brine is 36 deg. F. What is the amount of refrigeration produced by the plant?

Answer.—Specific heat of brine at 13 deg. Baume, that is, containing 15 lbs. Ca Cl. per cubic foot is 0.884. The quantity of brine passed by the pump per day is equal to the stroke volume of the pump multiplied by the number of strokes and by the number of minutes in a day. This is equal to $8 \times 8 \times .7854 \times 10 \times 60 \times 24 = 723{,}830.4$ cubic inches.

Specific gravity of brine = 1.103 and .036 pound.

Weight of brine is therefore $723830.4 \times .036 \times 1.103 = 28{,}742.016$ pounds.

The temperature through which the brine is raised is 36—10 = 26 degrees. The total number of thermal units absorbed by the brine is number of pounds $\times$ specific heat $\times$ range of temperature $= 28742.016 \times .884 \times 26$. Tons of refrigeration is

$$\frac{28742.016 \times .884 \times 26}{288{,}000} = 2.293 \text{ tons.}$$

* * *

Question.—What would be the capacity of a plant with a compressor 16×32 operating at 50 r.p.m. under 185 pounds head and 15.67 pounds back pressure?

Answer.—Area of compressor piston is $16 \times 16 \times .7854 = 201.06$ sq. inches.

Compressor displacement = area of piston $\times$ stroke $\times$ strokes per minute $= 201.06 \times 32 \times 50 \times 2 = 643{,}392$ cubic inches $= \frac{643{,}392}{1728} = 372.3$ cubic feet per minute.

With a displacing efficiency of 90 per cent., this becomes $372.3 \times .90 = 335.07$ cubic feet. Specific volume of ammonia at 15.67 pounds pressure is 9.3 or 9.3 cubic feet of vapor = 1 pound. The number of pounds of ammonia evaporated is, therefore $\frac{335.07}{9.3} = 36.03$ lbs.

Latent heat of ammonia at back pressure of 15.67 pounds is 566.

As the temperature of ammonia entering the expansion coil must be lowered to that of the expanding vapor, the cooling effect necessary to do this, or in other words, the heat of the liquid, must be subtracted from the gross cooling effect of the vaporization. The heat of the liquid at 185 pounds is + 71 B.t.u., and the heat of the liquid at 15.67 pounds is — 35 B.t.u. The difference is 106 B.t.u.

The net cooling effect of the expansion of one pound of ammonia is therefore 566 — 106 = 460 B.t.u. The amount of ammonia evaporated per minute is 36.03 pounds. Cooling effect per minute is therefore $460 \times 36.03 = 16573.8$ B.t.u. One ton of refrigeration effect is equivalent to 200 B.t.u. per minute. The capacity of the machine is then $\frac{16573.8}{200}$ = 82.869 tons.

Progress in New Equipment

RECENT DEVELOPMENTS IN BLAST FURNACE BLOWING EQUIPMENT

AFTER the general adoption of the steam turbine in large central power, the erroneous impression gained ground that the replacing of the reciprocating blowing engine by the turbo blower could only be a question of a comparatively short time. This expectation of the uninitiated was not realized and it is doubtful if it will ever be realized.

The same laws of nature which give the steam turbine advantages over the steam engine, are obstacles in the case of the turbo blower. Firstly, the steam turbine excels the steam engine only in the region below atmosphere, and in the compression of air for blast furnace use this region is absent, because, naturally the compression must start with atmospheric pressure. Secondly, the losses in the earlier or high pressure stages of the steam turbine are converted into heat which can be utilized in the latter stages, while in the turbo blower the losses in the early or low pressure stages mean additional work to be done in the latter stages. Thirdly, the steam turbine utilizes the highly efficient process of converting pressure into velocity, whereas, the turbo blower tries to utilize the very inefficient process of converting velocity into pressure. Fourthly, the central power station utilizing large turbo generators, makes power for the sake of selling it. High steam pressure, superheat and vacua which are impracticable around a blast furnace, can be introduced in the central station. Larger and larger units can also be installed, whereas the size of the turbo blower is limited by the size of the blast furnace.

While for these very reasons engineers with knowledge of the underlying principles always had their doubts concerning general adoption of the turbo blower, another rather unexpected reason has considerably delayed and hindered its introduction. The reason in question is, incorrect governing of the blower and consequent dusting of the furnace. The turbo blower is a machine supposedly free from pulsations, and great advantages were expected from a steady stream of air going to the furnace. But practice has shown that, quite on the contrary, the vast majority of turbo blowers vary in volume delivery a much greater amount than reciprocating blowing engines do. The amount of ore lost by dusting due to this fluctuation of air supply is so great that most blast furnace managers are, at the present time, afraid to install turbo blowers.

In blowing engines the course of development likewise has been following rather unexpected lines. By comparison of the number of new furnaces built with the number of new blowing engines and new turbo blowers installed, it is found that a comparatively small amount of new blowing equipment has been added. This surprising result is explained by the fact that a very large number of existing blowing engines have been rebuilt in such a way as to have a larger capacity and to serve a greater number of furnaces than heretofore. The possibility of increasing the capacity of existing blowing engines is largely due to the increase in piston speeds made possible by the introduction of plate valves which have been mentioned before in our columns. A great amount of rebuilding of existing blowing engines has been done by the Mesta Machine Company of Pittsburgh, Pa., with plate valves manufactured under Iversen patents.

The so-called rebuilding of blowing engines is, in some cases, limited to the simple replacing of the existing valves by automatic plate valves. In other instances it means more than that, namely, the removing of old cylinder heads and replacing them by heads containing plate valves. In the most extreme cases it means the removal of the whole air end including the air cylinder.

FIG. 1. PLATE VALVES ARRANGED IN CAGES TO REPLACE LARGE POPPET VALVES PREVIOUSLY EMPLOYED.

An illustration of the methods employed in replacing an old type of valves by plate valves is shown on Fig. No. 1. Here are seen plate valves arranged in cages, which take the place of large poppet valves, originally operating in the head. The cages are dished in order to reduce clearance to a very small amount. In many cases the clearance volume is smaller than it was with the original valves, while in other cases it is increased slightly, depending upon the type of valves being replaced by the cages. But even in this latter case, the advantages gained by the instantaneous opening of the valves, and the larger area secured, are so overwhelming, that the slight

FIG. 2. SHOWING HOW VALVES HAVE BEEN MADE TO FIT A PREVIOUS SEGMENTAL ARRANGEMENT.

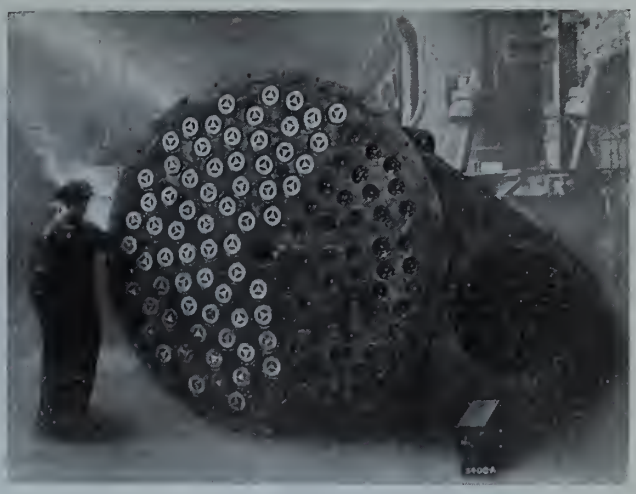

FIG. 3. ILLUSTRATING METHOD OF INSTALLING PLATE VALVES IN PLACE OF EXISTING VALVES IN THE HEAD.

increase in clearance volume fades into insignificance.

The arrangement of the valves in cages offers several advantages. The removal of one cover plate exposes all outlet valves of the cage to inspection on the delivery side. The inlet cages are made in two parts so that the removal of one cover and the top of a cage exposes all the valves of that cage to inspection. In the extremely rare case of breakage of a valve, the whole cake can be easily removed and replaced by a spare one.

Fig. No. 2 shows how valves have been made to fit a segmental arrangement of old valves. Fig. No. 3 illustrates the method of installing valves in place of existing valves in the head. This latter method as a rule gives some increase in valve area, but not enough to warrant increasing the speed of the engine materially. This method is to be recommended particularly in the case of old blowing engines equipped with leather valves. The advantage is twofold: first, the plate valves are always tight and in consequence deliver more air, whereas leather valves soon begin to leak, due to warping or charring of the leather; second, higher pressure can be blown.

The second method, namely, that of replacing old air heads with new ones, ist very widely practised at the present time. Fig. No. 4 shows the appearance of such air heads. The third and last method, namely, that of replacing the old air end has been necessary only very occasionally. Fig. No. 5 shows the appearance of such an air end.

Mention has already been made of the fact that plate valves allow higher piston speeds. This feature is beneficial in several ways. Right now, due to the poor trade of coke available, many furnaces are troubled by the necessity of more air than was used in the past when better coke was on hand. Increasing the supply of air has pulled several furnaces out of a bad predicament. More air means not only more pig iron, but in addition, more furnace gas, more steam and steady profitable operation.

The installation of plate valves, and the resulting possible increase in speed of the blowing engines, has enabled a number of plants to erect another furnace without installing additional blowing units. The heretofore customary practice of blowing a furnace with three or sometimes four tubs, has given way to the present possibility of blowing a furnace with two tubs only; and, in fact, a great many furnaces in this country are being blown to-day, using only two 84 in. diameter blowing tubs equipped with automatic plate valves. From this it can be seen that the blowing capacity of existing plants can be increased 50 to 100 per cent. by equipping the present engines with automatic plate valves.

CONTINUOUS CO_2 INDICATOR

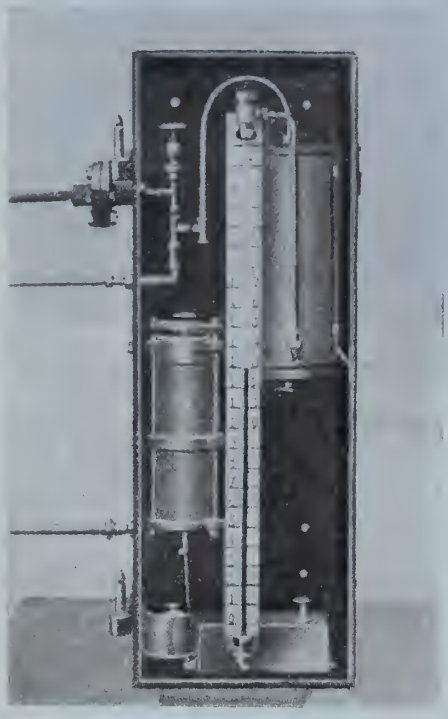
A NOVEL type of combustion analysis apparatus is illustrated in the accompanying engravings, the principal features being the absence of solutions and moving parts along with simplicity of construction and facility of operation. Referring to the diagram, it will be seen that, after passing through a filter, the flue gas enters a gas chamber in which is mounted a porous pot containing a cartridge of absorbing chemical. The inside space of the gas chamber is connected to the well of a fluid indicator having a graduated scale tube, the upper end of which connects with the space inside of the porous pot.

Passage of the gases through the apparatus is induced by a small steam aspirator, which operates continuously, and as the gases pass over the porous pot at

FIG. 4. REPLACING OLD AIR HEADS WITH NEW ONES.

FIG. 5. NEW AIR ENDS WHICH HAVE REPLACED OLD ONES.

a uniform rate, a constant amount passes into the interior and comes in contact with the absorbent which removes the carbonic acid gas, and thus causes a drop in the gas pressure surrounding the



CONTINUOUS COMBUSTION INDICATOR WITH VACUUM CONTROLLED COLUMN OF LIQUID AND GRADUATED SCALE.

cartridge. This drop in pressure causes the colored liquid in the well to rise in the graduated tube in corresponding degree, the liquid being maintained at the same height as long as the proportion of CO_2 in the flue gas remains constant.

The instrument is read as easily as an

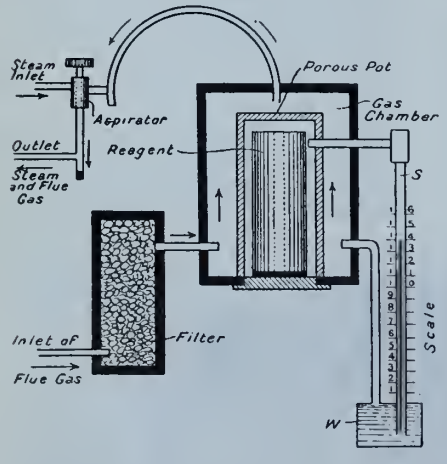


DIAGRAM ILLUSTRATING ACTION OF COMBUSTION INDICATOR.

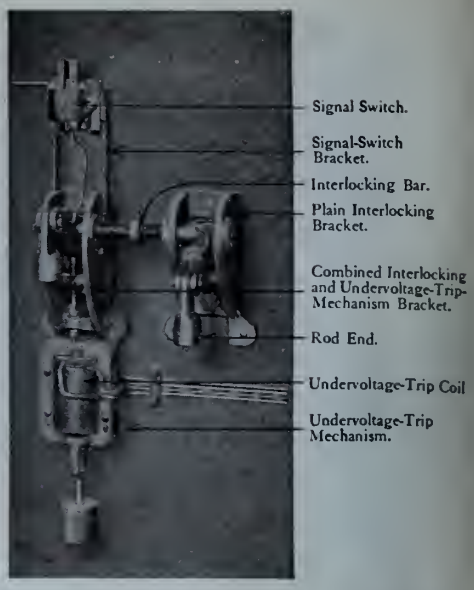
ordinary thermometer, and requires no further attention than the renewal of the absorbing chemical, which is done every few days at a weekly cost of about 25 cents. The apparatus is made by Holdsworth & Sons, Ltd., Bradford, Eng., and has an accuracy within one-half of 1 per cent. of the well-known Orsat apparatus.

OIL CIRCUIT-BREAKER ACCESSORIES

BULLETIN (DS272) recently issued by the Westinghouse Electric & Manufacturing Co., under the title of "Oil Circuit-Breaker Accessories" contains information regarding every combination of tripping and signalling likely to be required. Trip-magnet frames and coils are listed for obtaining underload, undervoltage, overload, over-voltage, series and shunt trip; several and, in some cases, all of these can be applied on the same breaker to act with the standard automatic overload trip mechanism.

For controlling the operating circuit of electrically operated breakers, central switches are listed. These can be connected with signal lamps to indicate the position of the breaker; one style has signal lamps mounted on its cover-plate. And to control the signal lamp circuits, "signal and shunt-trip cutout switches" are shown. These can be so connected as to light the proper lamps to indicate the position of the breaker at all times; they are also used to open the shunt-trip circuit when the breaker opens.

With a double-throw breaker, or with two single-throw breakers connected as a double-throw breaker, it is often desirable to have the throws so connected that with one throw closed it is impossible to close the other, and vice versa. This can be accomplished on electrically-operated breakers by interconnecting the operating circuit through a "signal and shunt-trip cutout" switch; with manually operated breakers, it is accomplished by an interlocking bar with a suitable bracket.



REAR OF SINGLE-HAND COVERPLATES OF TWO INTERLOCKED BREAKERS.

And there are described and listed: signal switches, inverse-time element attachments; bell-alarm signal-contact attachments; bell-crank accelerating devices; universal mounting brackets for mounting breakers, instrument transformers, and other accessories on the rear of the panel or on a separate pipe or angle-iron frame.

The Victor Cleans Up Again

(Both literally and figuratively)

It is a common occurrence for us to hear of a "Victor" Tube Cleaner that is making some record in the plant where it is being used—a record amount of scale that has been removed, a length of time the Cleaner is used without any repairs, or a record for speed (number of tubes cleaned) as compared with some other cleaner.

Of the many reports of this kind that are received, the following from the Chief Engineer of a large Railway and Electric Company is particularly interesting, because of the great amount of time saved by using a "Victor" Cleaner.

This Chief Engineer wrote us under date of May 5th as follows:

"We received the 3¼ in. Air Tube Cleaner during the last few days in March. It was placed in real service about April first. We take pleasure in informing you that we have subjected the machine to the most rigid tests and find it satisfactory in every detail.

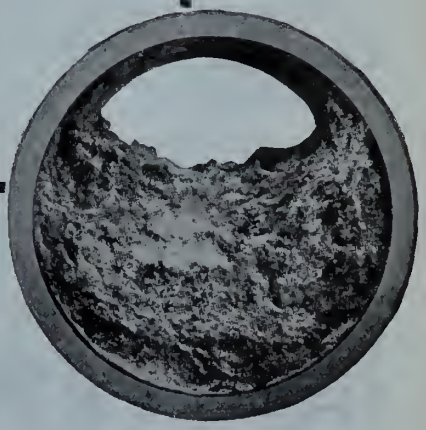
"We find in using the Water machines in a badly scaled tube that the water could not find outlet. This caused a slowing down of the machine, making it very ineffectual. As a sample of this, we had a Water machine working in a boiler when the Liberty Air machine arrived, and it took eight hours to bore one tube with the Water machine. We placed the Air machine in the next tube which was in the same condition, and it was thoroughly cleaned by the Air machine in ten minutes.

"It is rather hard, on account of our operating conditions, to give an exact estimate of the time saved with the new machine, but think I am quite conservative in saying we can thoroughly turbine a boiler in one-fourth the time it took with the old equipment."

For operation with air or steam, the "Victor" stands without an equal for speed and endurance, and these are the things that count. The "Victor" is described in Catalogue "H."

If you want to win, get a thoroughbred — that's the "Victor." It's built for endurance and speed.

Liberty Manufacturing Company
6904 Susquehanna St., Pittsburgh, Pa.



Yes, this tube is badly scaled, but its condition is no worse than some of the tubes that were cleaned in the plant mentioned above.

TEN YEARS AGO AND TODAY

Old style Rotor permanently abandoned seven years ago.

Ten years ago—before we brought our Turbine to its present high degree of perfection—the manufacturing difficulties made it impossible to produce a solid rotor without semi-circular slots. These slots are acknowledged as highly undesirable and built-up rotors are never made with them. We finally invented and patented a process of manufacture whereby we were able to eliminate the slots and today unslotted buckets in solid rotor are AN EXCLUSIVE STURTEVANT FEATURE.

The unslotted bucket is obviously much stronger and permits of a thinner and more efficient vane. Furthermore it is self-evident that the slots encourage leakage from one bucket to the next and this further reduces the efficiency.

The unslotted bucket is just one of the superiorities of the Sturtevant steam turbine. The other advantages are given in detail in our catalogs 209 and 210, copies of which will be sent on request.

Improved Sturtevant Rotor—Cannot be duplicated due to patents.

TRADE GOSSIP

Granby, Que.—The Southern Canada Power Co. will build a sub-station and office here.

Alvinston, Ont.—Town Council contemplates the installation of an electric lighting system.

Aylmer, Ont.—The Town Council will purchase electrical transmission equipment, motor-driven pumps, etc.

London, Ont.—E. Leonard & Sons, York St., contemplate the erection of a blacksmith shop to cost $20,000.

Prince Rupert, B.C.—The City contemplates extending the water main system which will cost $10,000.

Rosthern, Sask.—The Town Council will install a power plant. The Perry Electric Co. of Edmonton have the contract.

Hamilton, Ont.—The Barton Township Council has decided to submit Hydro-Electric and enabling by-laws to the ratepayers.

St. Mary's Ont.—The Town Council are building an addition to the civic power plant and are in the market for a motor driven pump.

St. Catherines, Ont.—The City Council are considering the purchase of a motor driven sewage pump. W. P. Near is the city engineer.

Bradford, Ont.—A by-law will be submitted to the ratepayers on Oct. 6, to authorize an expenditure of $15,600 on installing a hydro-electric transmission system.

Chapleau Township, Ont.—The Township Council will build an addition to its pumping station and instal an electrically-operated pumping unit to cost $6,000.

Toronto, Ont.—The City Architect has issued a permit to the Hospital of Incurables to install underground fuel oil storage system, 130 Dunn avenue, at a cost of $3,000.

Welland, Ont.—The voltage of the Hydro-electric system here will be increased from 12,000 to 46,000 volts and the equipment in the sub-station is being changed to suit the new service.

Scarborough, Ont.—The Hydro-Electric Power Commission has notified the Township Council that work has been started on a line to go through Birchcliffe, Scarborough Junction and Agincourt. It is hoped to complete the work this fall.

New Toronto, Ont.—Building operations have been already commenced on the new hydro-electric sub-station at the corner of 9th street and Birmingham avenue, New Toronto, by Witchall and

Lethbridge, Alta. — Commissioner Freeman stated recently at a meeting of the City Council that a new steam turbine and generator will have to be ordered without delay in order to provide power for the increasing load. It is estimated that a new unit will cost $50,000.

The Kerr Engine Co., of Walkerville, Ont., valve manufacturers, have leased their iron foundries to the Standard Foundry & Supply Co., who will hereafter make all the grey iron castings for the Kerr firm in connection with their extensive valve and hydrant business, and will also go strongly into jobbing work.

The St. Lawrence Welding Co., of Montreal, have opened up their new brass foundry at 39 Olier Street. The plant is equipped on a large scale with all the latest brass foundry requirements and production of castings has recently been started. The firm has secured the services of Robert Stark, who is one of the best known foundry men in Canada, and who will have charge of the brass foundry under the direction of A. M. Barry.

Brandon, Man.—The sale has been completed of the properties of the Brandon Electric Light Co. and the Brandon Gas & Power Co., to the Canada Gas & Electric Corporation, a company composed of financial interests in the City of Cleveland. G. A. Paterson, who for the last twenty-five years has been managing director of the Brandon Electric Light Co., has been appointed general manager of the new corporation's properties in Brandon.

Ladysmith, B.C.—The smelter which was recently put in operation by the Ladysmith Smelting Corporation, will be capable of handling 1,200 tons of ore per day, although the initial capacity is 700 tons. There are two blast furnaces, one 42 in. x 120 in., and the other 42 in. x 160 in. at the tuyeres. The boiler plant consists of two 80 h.p., one 88 h.p., and one 104 h.p. boilers. Two electric generators furnish power for the motors and lighting system.

Hamilton, Ont.—The following tenders have been submitted in connection with the proposed pumping installation for the Beach Station:—Allan General Supplies Co., $3,715; Canadian General Electric Co., transformers, $14,010; DeLaval Co., centrifugal pumps, $22,420; Canadian General Electric Co.. switching apparatus, $4,990; Canadian Westinghouse Co., motors, $16,620; Babcock & Wilcox Co., boilers and insulation, $17,555; Turbine Equipment Co., steam turbine pumps, $52,517. The original estimate for the pumping equipment was $127,000.

Sherbrooke, Que.—The Southern Canada Power Co. is building 88 miles of high tension transmission lines, connecting up the cities of Sherbrooke, Magog, Waterloo, Granby and St. Johns. It is expected that these lines will be completed this fall. When completed this will give the company over 160 miles of high tension transmissions, principally 50,000 volts. The company have recently purchased property on the main street in Granby, almost opposite the Post Office, and are erecting a new sub-station, office and store for the sale of electrical equipment.

CATALOGUES

The Vanadium Alloys Steel Co., Pittsburgh, Pa., has mailed to the trade the latest stock list of "Red Cut Superior" high-speed steel in warehouses at Pittsburgh, Pa., and Latrolie, Pa.

Reducing Valves.—Bulletin issued by Chaplin-Fulton Mfg. Co., Pittsburg, Pa., describes the "Fulton" steam reducing valve, and also gives directions for setting and operating this device. Two types are illustrated together with prices for the various sizes.

Cheap Steam.—The May issue of the organ "Cheap Steam" has been mailed by Ed. Bennis & Co., Little Hulton, Bolton, England. This publication contains a short descriptive article covering power plants where Bennis stokers are installed and other matter of interest to steam users.

Knudsen Packless Joints.—Bulletin issued by the Universal Valve Co., Burlington, Vt., describing the Knudsen packless swivel joint for iron pipe in steam, gas air or ammonia lines. The advantages claimed for this joint and details of its construction are dealt with fully, while a number of views are included showing applications under various conditions.

The Crane Packing Co., Chicago, manufacturers of the well known "John Crane" flexible metallic packing for all vapors and liquids, announce the establishment of their Eastern office in the Woolworth Building, New York City. Their engineer, A. W. Payne, with much experience with packing problems in the oil, mining and industrial fields, has been placed in charge of this branch.

Radial Brick Chimneys. The Alphons Custodis Chimney Construction Co., New York, have gotten out an interesting bulletin showing a number of tall chimneys which they have constructed, with principal dimensions. The bulletin also contains details of the radial brick used and a copy of Kent's table of size of chimneys for steam boilers.

Pulleystone for Belts.—Bulletin distributed by the National Chemical Works, South Acton, London, England, deals with the material "Pulleystone" for coating main driving pulleys and for other purposes where belt dressing is used. The main advantages claimed for this material are given in detail. Reference is also made to a material named "Permanite" for making joints and repairing cracks in metal articles.

Boiler House Elevators is the title of a 28 page catalogue recently issued by the Ed. Bennis & Co., Little Hulton, Bolton, England. The catalogue after dealing with the advantages of elevating and conveying machinery in boiler plants, proceeds to describe the "Bennis" elevator, drawing attention to its principal constructional features and also to the economies that can be effected by its use. The greater part of the catalogue comprises several very clear views, covering a number of installations showing the wide field of application. A brief description accompanies each illustration detailing the chief points of interest.

The Sanford Riley Stoker Co., of Worcester, Mass., has had such an increased volume of business in the Riley underfeed stoker, that it has arranged for additional manufacturing facilities in Detroit, Mich.

This trap can be installed in any position desired as it has two outlets.

This is a remark very often made by users in reference to—

The LONG Patent Steam Trap

Has But One Moveable Part

Valve is actuated by the expanding and contracting of a tube, a motion that is positive and of sufficient force to close the valve against a pressure of two hundred pounds.

The Long Trap is automatic and requires no valves except those which control admission of steam to apparatus to which trap is attached. It is capable of draining from 900 to 1,500 feet of one-inch pipe.

There are other superior points about the Long Steam Trap. as it could be used as a condenser for heating water for washing bottles, etc., and still remain a trap. Let us tell you the complete story of this wonderfully successful power house facility.

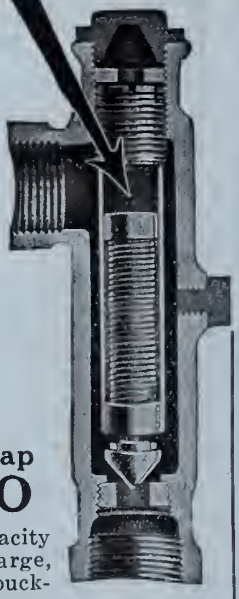
100% AUTOMATIC STEAM TRAP SARCO OPERATED BY ITS OWN HYDRAULIC PRESSURE CREATED HERE



In addition to the increasing costs of fuel—the scarcity of supply and difficulty of delivery add to the necessity for saving.

Put one of these wonderful little, highly efficient 100% automatic steam traps on every steam line.

The Steam Trap SARCO

has equal capacity with the large, cumbersome bucket or float traps, yet is only slightly larger in diameter than the pipe to which it is attached. It requires no building up nor platform, but may be added as a bend or elbow in any convenient position.

Once installed, the Steam Trap SARCO requires no further care or attention. It operates entirely from the hydraulic force created within the power cartridge inside the trap

The Steam Trap SARCO will save money for you from the start. It costs less, operates automatically and saves steam and fuel.

Will you give us the opportunity to prove our claims.

Sarco Company, Inc.

Woolworth Bldg.

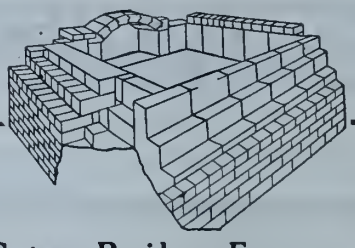
and all principal cities.

Iron Works. There will be no change in the management or policy of the Murphy Iron Works. They will continue the manufacture of the Murphy automatic furnace, increasing their manufacturing facilities as required for the production of Riley stokers. R. Sanford Riley, of Worcester, Mass., has been elected president of the Murphy Iron Works. The B. F. Sturtevant Co., of Hyde Park, Mass., will continue to manufacture and act as selling agents for the Sanford Riley Stoker Co.

Machine Stoking.—A new catalogue entitled "Recent Developments in Machine Stoking," has been issued by Ed. Bennis & Co., Little Hulton, Bolton, England. The opening pages contain a description of the "Bennis" patent improved smokeless chain grate, including matters relating to its durability and draught feature. Following are a number of views showing important installations, each briefly described. The catalogue also contains several sectional views of Bennis chain grates under various types of boiler. An interesting table is shown giving results of tests of this stoker under different types of boiler. The concluding pages contain a table of sizes of Bennis Chain grate stokers and also a table of properties of saturated steam. The catalogue contains 39 pages and is gotten up in attractive style.

SHUNT-WOUND direct-current electric motors are particularly suitable for driving machinery in which the load varies, but which, nevertheless, requires a constant speed. On the other hand, series-wound direct-current motors are not so suitable for belt drives, or where the load is apt to fall suddenly. Differentially wound motors are compound-wound machines, with the series winding arranged to oppose the action of the shunt winding instead of assisting it, as in the normal compound-wound motor, thus giving a speed that is practically constant between no load and full load. With compound-wound direct current motors the speed at no load and full load differs from 15 to 30 per cent., according to the amount of series-winding employed. The advantage of this type of motor is that a larger starting torque is obtained than with shunt-wound motors.



Gates Boiler Furnace
Patented 1916

Will last three times as long as ordinary good grade Fire Brick. These blocks are inter-locking, and made so that any handy man or fireman can renew them without disturbing any of the other brick work.

Canadian Shipments Made from our Warehouses at Toronto

A great many Canadian Manufacturers say that our claims are facts. We base our claims on a thorough knowledge of the requirements of lubricating oils coupled with scientific preparation. We claim that Kellogg Non-Corrosive Cylinder Oil will eliminate friction; that, owing to its perfect nature the highest efficiency in lubricating is attained; it will last longer, because it is pure, less oiling required; reduces your coal bill very noticeably, because the engines run easier, and every atom of power gives its maximum amount of use. Is your oil living up to your requirements? This Canadian reputation is founded on long experience.

Waukesha Brewery

A thoroughgoing job of protection for machinery, walls and floors achieved with various "R.I.W." Protective Products as described below.

A Power Plant To Be Proud Of

Every machine in the Waukesha Brewery is coated with "R.I.W." Machinery Enamel. It is the spick and spannest looking outfit a power house engineer ever had the pleasure of seeing, thanks to

R.I.W. REMEMBER ITS WATERPROOF — REG. U.S. PAT. OFF. **PROTECTIVE PRODUCTS**

The Waukesha Brewery has floors that will not disintegrate or "dust" and cause injury to machinery bearings. These floors are protected and given a fine appearance by the use of "R.I.W." Cement Filler and Cement Floor Paint. (Patented as to Portland Cement, Feb. 27, 1906). They are impervious to oil, grease, water, acids or alkalies.

The walls are damp-proofed with No. 232 "R.I.W.," and are further protected and decorated with "R.I.W." Liquid Konkerit. (Pat'd as to Portland Cement Feb. 27, 1906.) The woodwork is made time and fume-proof with sanitary, beautiful "R.I.W." Hospital and Laboratory Enamel.

All steel work is protected with No. 49 "R.I.W.," and all other metal work with "R.I.W." Aluminum Bronze.

Then, to finish up this model of protection against all forces of corrosion and disintegration, all wainscoting in the engine room and brew house is decorated and preserved with "R.I.W." Flex-Sicco Ready Mixed Paint.

This plant is worth any power man's study. Write for our literature, Dept. 59.

CANADA'S DEPARTMENTAL HOUSE FOR MECHANICAL GOODS

This book should be in the hands of every pump user. A postal will bring your copy promptly

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs*. Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

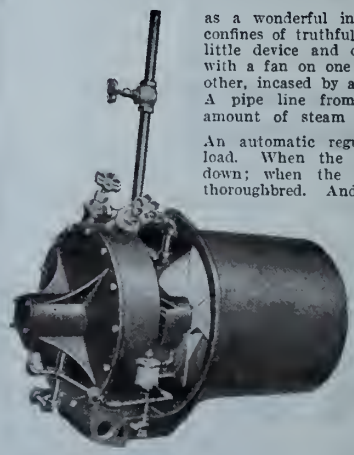
We believe we are "doing our bit" in demonstrating to manufacturers how they can effectively cut down the cost of steam production, better their combustion and increase the capacities of their boilers. In offering the

Coe Turbine Blower



as a wonderful invention, we are well within the confines of truthful advertising. It is such a simple little device and does such a big work! A shaft with a fan on one end and a steam turbine on the other, incased by a shell is about all there is to it. A pipe line from the leader supplies the small amount of steam required.

An automatic regulator adjusts the speed to the load. When the load is light, the blower slows down; when the peak comes it responds like a thoroughbred. And how it does drive the air into the fire! Clinker doesn't get a chance to form.

The gases of combustion which ordinarily pass up the chimney are held back by the draft controller, thoroughly mixed with the air and burned. Nothing gets away that is worth keeping.

Space limits prevent a complete description of the Coe Turbine Blower. Write for it and receive our special demonstration proposition. You should have it. We solicit your inquiry.

Jefferson Unions

The *Dependable* Pipe Connections

No matter where you put a Jefferson Union, whether it be on an air line, a steam line, a gas line, or oil line—it's "on the job" at the last turn of the wrench. You can forget its existence—for it's dependable—it will keep energy where it belongs, in the pipes. There are numberless styles of Jeffersons—one for every kind of connection. And there are two types, one with brass-to-iron ball seat and one with iron-to-iron seat for where the prevention of corrosion is not essential.

You had better get the Jefferson Book "Unions" —the coupon below mailed to-day will bring it to you at once.

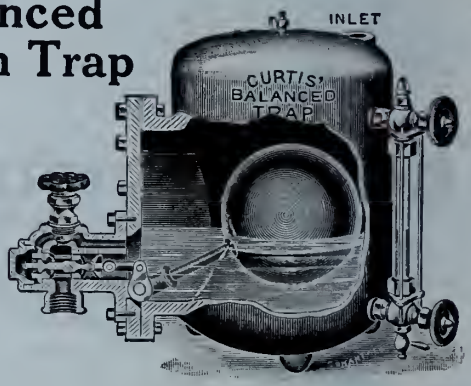
GURTIS Engineering Specialties

Balanced Steam Trap



This trap is often used as a waterline trap on large plants where there is need to balance any particular circulation to prevent snapping and cracking in pipes and radiators.

This Trap Has These Points of Difference and Superiority

1—A perfectly balanced valve.
2—An absolutely frictionless valve.
3—The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4—The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5—Each trap will operate perfectly on pressure varying from one to 250 lbs.

The great merit of this trap, its simplicity, its dependability and serviceability make it well worth being better acquainted with. Send for special printed matter describing it and giving prices. Address the Manufacturers.

Repairs?
—simply regrind the seating surfaces

and a Lunkenheimer Regrinding Valve is as tight as when new.

The exceptional wearing qualities of this valve are well known to the trade. Its metal to metal seat—ground to a tight fit, forms an ideal seat to resist the inevitable wearing action of steam at its high velocity. And the fact that the seating surfaces can be *reground*—an inexpensive operation easily accomplished, makes the renewal of parts with the cost it entails, wholly unnecessary.

The Lunkenheimer Regrinding Valve is truly an economy valve. All the parts are designed to resist wear—they are generously proportioned, the machining is accurate and the composition for the different parts varies according to the duty the part performs.

The threads are long and cut perfectly true. The stuffing box is provided with gland follower on sizes above one-half inch and is packed with a moulded asbestos ring packing which is exceptionally durable. Should necessity require it can be repacked while under pressure and wide open.

Made in a variety of types, including Globe, Angle and Cross, with Inside Screw and with Outside Screw and Yoke. Also Horizontal, Angle and Vertical Check Valves.

We cannot make all, but—we do make the best

Your local dealer can supply you; if not, write us. Write for descriptive booklet No. 517-DC.

Man-Size Conversation

Something about Jones---The Test Question that Silenced Jennings---Where Jones gets the information that makes him listened to when he speaks.

AFTER the little group had finished their cigars, and were about to separate, each going his own way, Brown said to Smith: "Wasn't Jones great? And didn't he put it all over Know-It-All Jennings?"

It was just such a group of men as you see gathered every day round a luncheon table, or in the club lounge; and the theme of the conversation was likewise common enough—the present business situation, and the probable situation when Peace is made.

At first every man had opinions to declare, but most of all Jennings. Jones was, at the beginning, the silent one. But at a point when Jennings, with his usual cocksureness, was voicing some extravagant views, Jones rather jolted him by asking him, "What is your authority?" And Jennings didn't have authority—nothing more than opinions.

It was then that Jones began to talk, and his tactful, well-informed views and statements instantly commanded the attention of every man round the table; for every man was learning. Even Jennings had the grace of keep quiet, for he knew he was listening to a better-informed man.

Jones has a staggering question to put to men with opinions which they express boldly and confidently. It is: "What is your authority? Your opinions are no better than your information." The average man expressing opinions doesn't possess much solid information; he just "feels" that way.

Every man not an idler is interested in Business—first, in his own business; second, in the Nation's business. Whether he be a retailer in a country town; or a manufacturer; or a lawyer advising clients on investments; or a bond-dealer needing to know much about the many factors that affect prices; or a banker; or a private investor whose funds, invested or waiting investments, are his main source of income; he is interested in Business, and he needs information—the real stuff which is the basis of opinion.

Where can each get the kind and amount of information desired?

Let him get it where Jones gets much of his information —from THE FINANCIAL POST OF CANADA.

Jones does a good deal more than just pay $3 to get this paper every Saturday; he *reads* it. To him the POST is the newspaper prized most of all. He sets aside a certain set time each week for reading it. It satisfies him because its views are based on information, and information is the POST'S chief material.

The POST keeps Jones soundly and broadly informed about the business affairs of the country. He finds that the POST takes a business-like view of all questions; that it is not influenced by any political factions or "interests," that it tells the truth whether the readers like it or not. He knows that little of importance will occur in connection with the business of the country without enlightening information or comment appearing in the POST.

He gets the best-informed news about listed and other securities, in the POST:—Milling, Transportation, Pulp and Paper, Iron and Steel, Electrical Enterprises; and so on. This weekly Security News he finds is of an authoritative character —usually signed—prepared by specialists, who, from the nature of their daily work, are in intimate touch with the factors that affect prices, and with high-up or well-informed men who have *knowledge.*

Jones finds no other paper in Canada attempting to give the service the POST does in relation to listed securities.

Jones finds the POST'S editorial page stimulating. He enjoys the biographical stories of Big Men which appear in the POST. The article each week by Agnes Laut gives him information gathered by one of the best informed and highest paid writers in America. In short, for Jones the POST is a treasury of information about Business; and it is Business by which Jones earns his bread and butter and something more.

When Jones mingles with his fellow men, and Business is the Theme of Conversation, most men are willing to listen to him, because his opinions are based on sound and reliable information.

Now, what is the application of all this? It is that you, the reader of this advertisement, may also make yourself a well-informed man about *Business—by reading THE FINANCIAL POST.* The $3 it costs per year is neither here nor there to the man who really wants to *know*—to have knowledge about matters and markets pertaining to his own business; and about the Country's business.

If you want your opinions to be well-informed; if you want a wide knowledge of Business; let the POST go to your home each Saturday. Sign the coupon below. Send no money now. Have the bill go forward in the usual way.

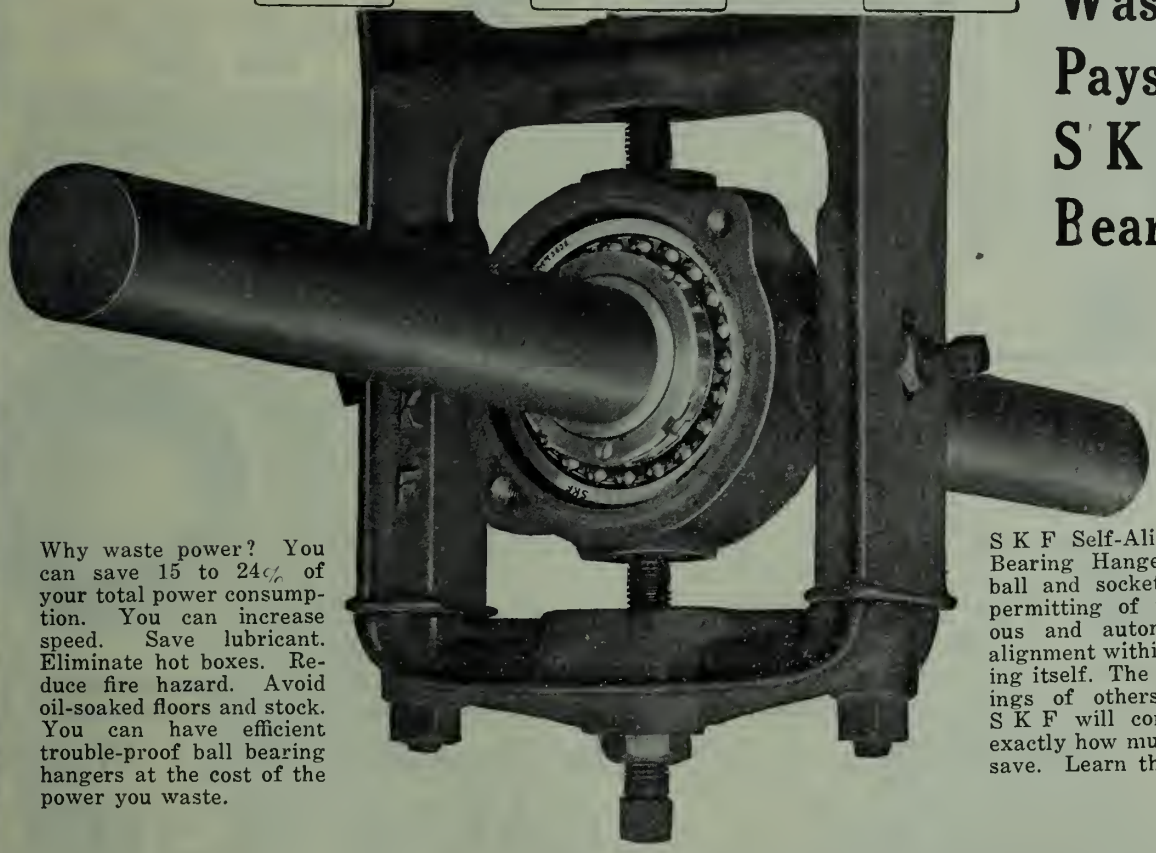
The Power You Waste Pays for S K F Bearings



Why waste power? You can save 15 to 24% of your total power consumption. You can increase speed. Save lubricant. Eliminate hot boxes. Reduce fire hazard. Avoid oil-soaked floors and stock. You can have efficient trouble-proof ball bearing hangers at the cost of the power you waste.

S K F Self-Aligning Ball Bearing Hangers on the ball and socket principle, permitting of instantaneous and automatic self-alignment within the bearing itself. The actual savings of others who use S K F will convince you exactly how much you can save. Learn the facts.

If you are having transmission troubles and wasting power needlessly—if you want to have a cleaner, better-looking shop—use S K F.

We will gladly send you complete literature and letters from some of the big S K F users. Ask us to send you the "EVIDENCE."

Expansion Trouble
Tube Trouble
Scale Trouble
GONE

The Result of Alberger Heater Design

A movable section containing the hot water tubes, expands independently from the movable section containing the cold water tubes. Simple? Yes—and one of the biggest Alberger Improvements over ordinary closed heater design. Easily a single tube can be taken out, if necessary. Nor is there need to break water and steam connections to secure access to the heating surface; these connections are on the body of the shell. Body of heater is built of highest grade cast iron, and the corrugated tubes are copper.

Write to-day for catalog illustrating both horizontal and vertical types.

SKF

BALL BEARING HANGERS

Six Months on One Oiling

To oil hangers but twice a year is a persuasive argument—a vast amount of oil, trouble and labor are certainly saved.

But do not overlook other savings. Think what the SKF oil-tight housing means—no oil-soaked belts, no oily floors, no goods spoiled in process by oil, reduced fire risk. Think of the safety to your employees, who no longer have to climb among moving belts, shafts and pulleys. Think of the greatest saving of all-bearing friction reduced 60 to 80%—a saving of 20 to 35% on total power.

Let us give you the service record of SKF made in scores of Canadian plants. Let us refer you to users near you. We would welcome the opportunity.

Wanted—

Engineers to contribute to Power House

THIS is a practical paper for practical engineers. It is an educational medium and out to help its readers. It is a technical school and a social meeting place combined. It is first, last and all the time an engineer's paper.

If you should meet two or three or a dozen of your brother engineers you would swap ideas—you'd tell of some idea you had worked out in your plant. Others would describe some pet schemes they had devised. And so you would be mutually benefited.

Why not make Power House your monthly meeting place? Why not describe in this paper some kink or scheme you have worked out and found successful? We will pay you for it and you, in turn, will be multiplying the usefulness of your idea five thousand fold!

Never mind polishing up your letters—just give us the idea; that's the main thing. Never mind how crude your pencil sketch may be. We have draughtsmen who will finish up your drawings so they may be reproduced.
Try this idea a time or two and see how much satisfaction you'll get out of it. Start the ball a-rolling and thus help other engineers, yourself and your paper.

14 in. Heart belt to weave room *29 in. GraKnight belt to basement*

Big Belts— For Big Jobs

There is one right way, and only one right way, to buy belting. That is on the basis of the *work to be done*. A big job needs a big belt.

If you buy it as you buy machinery — you will standardize it, as you have standardized your machinery. You will buy Standardized Belting.

Standardized Belts are made to the actual standards of the job. They have been worked out during sixty-six years of belting experience. The requirements of every kind of power transmission have been classified and a Standardized Belt evolved to meet the actual demands of each.

There is Graton & Knight Heart Brand, the standardized extra-heavy oak-tanned center stock belt — GraKnight, the standardized, medium-weight, oak-tanned center stock belt — GraKnight Dynamo, the standardized, light-weight, oak-tanned center stock belt—Neptune, the standardized, water-proof belting — Spartan, standardized for exacting conditions or difficult drives.

The way to save money on belting isn't to buy cheaper belts—but to buy the belt that will do your work best.

Apply Standards to your power Transmission. Our Engineers are at your service—let them help you standardize your belting.

GRATON AND KNIGHT

OVER 50,000 COPIES PER MONTH

Canadians

should be thankful that our Country has a Canadian Magazine fit to take its place in the company of the big American magazines — a magazine equalling in interest and literary merit the big magazines produced in a Country of 100,000,000, where it is possible to obtain $1,000 to $5,000 a page per issue or more for advertising space.

THE making of MACLEAN'S MAGAZINE month by month, year after year, has been hard labor. One difficulty was to get the right sort of matter—Canadian in origin and theme. A few years ago our country possessed few writers and artists of trained and high ability. To-day, thanks very largely to MACLEAN'S MAGAZINE, we have men and women writers and artists producing first-class work; they developed when they found a medium demanding a grade of work equalling the best contributors to American magazines. Also, the Canadian writers and artists who were finding a market for their wares in the United States turned to MACLEAN'S when this magazine showed itself to be a sufficient and creditable vehicle for their work.

The future has a good crop of A1 Canadian writers and artists in store, whose work will appear in MACLEAN'S; but consider these names of Canadian men and women who have already "arrived," and whose work appears in MACLEAN'S MAGAZINE:—

Sir Gilbert Parker,	E. Phillips Oppenheim,
Arthur Stringer,	Peter McArthur,
Arthur E. McFarlane,	L. B. Yates,
Stephen Leacock,	Geo. Eustace Pearson,
Robert W. Service,	W. A. Craick,
Alan Sullivan,	H. F. Gadsby,
Agnes C. Laut,	C. W. Jefferys,
L. M. Montgomery,	J. W. Beatty,
"Janey Canuck,"	Arthur William Brown,
A. C. Allenson,	Lou Skuce.

These are some of the names of Canadian men and women—writers and artists—who are doing work of the highest class, acceptable to the hardest-to-get-into publications of the United States. Ten years ago such a Canadian galaxy had no existence.

BESIDES these professional writers and artists—men and women who depend on their pen and pencil and brush for their livelihood—is a big host of others who write only when successfully urged to do so—because they have something to say that is worth saying. These are usually men in a big way of business, or professional men at the top of the ladder, or men and women doing unusual work of a most important sort—often obscurely because they are not self-trumpeters of their achievements or labors. For example, such men and women as:—

THE LATE SIR MORTIMER CLARK
JOHN BAYNE MACLEAN
ERMAN J. RIDGWAY
LORD NORTHCLIFFE
JOSEPH MARTIN, M.P.
BILLY SUNDAY

All these have contributed under their own name or a nom de plume to MACLEAN'S MAGAZINE in the last 12 or 15 months, recognizing that this magazine can give their messages to the whole nation, and to a class of persons whom they wish to reach.

NOBODY who knows MACLEAN'S would ever call it a story magazine, but rather a national magazine—almost a news magazine. Stories there are in every issue—enough of them to satisfy the right and natural desire for romance, adventure, achievement, business, love and intrigue. But the greater part of the contents of every issue of MACLEAN'S MAGAZINE may be called NEWS—NEWS of men and their work and triumphs; news of the nation's work and workers; news of discoveries; news of movements; news of politics; news of the builders and building of Canada. MACLEAN'S, as Canada's National Magazine, prepared for thinking and intelligent men and women, must be an informative and interpretive magazine, must mirror national opinion, record national affairs and developments, and be the VOICE of prophets, statesmen and leaders. MACLEAN'S is a magazine of to-day—a newspaper of a sort, dealing with big news passed over by daily newspapers whose function is the recording of the day's news—passing news; and who leave the fuller statement—the summed-up presentation of things they can but touch on—to MACLEAN'S MAGAZINE.

A Magazine *of* Power

News features of MACLEAN'S MAGAZINE greatly liked by its 50,000 readers are

The Business Outlook—article.
The Investment Situation—article
The Review of Reviews Department.
The Nation's Business.
Women and their work.

These are regular department features appearing in every issue of MACLEAN'S. They are of the nature of surveys or digests, and perform a service welcomed and praised by all readers who aim to keep themselves broadly informed concerning what's doing in Canada and what's being thought and said and done the wide world over.

REVIEW of Reviews is the outstanding feature of MACLEAN'S, in that it gives the best articles, in condensed form, from the best magazines of the world. A staff of trained people read and study the contents of all magazines and select for each issue of MACLEAN'S twenty or more articles which mirror the world's progress and present the changing aspects of world opinion.

IN rounding out this presentation of Canada's National Magazine a brief reference may be made to one large and discriminating and important class of contributors to it—advertisers. Literally hundreds of them employ MACLEAN'S for their advertising, to reach the influential classes represented by MACLEAN'S list of subscribers, and because they get national publicity economically. These makers and producers of goods of national consumption appreciate the fact that a select circulation of 50,000 gives them, among the most important families of Canada, strong local publicity as well as broad national publicity, and that retail distributors are both canvassed and assisted by their national advertising in MACLEAN'S MAGAZINE. They recognize that $1,000—$3,000 invested in space in MACLEAN'S MAGAZINE to buy 365-day national influence is dirt cheap publicity.

THIS is but condensed presentation of MACLEAN'S MAGAZINE. Very much more can be said about its editorial policy and character, about its making, about its quest for and development of new contributors, about the policy that keeps canvassing methods and advertising columns clean, about the hearty approval of subscribers of MACLEAN'S MAGAZINE, about the significance of 50,000 circulation, about the wisdom of doing a "little advertising in a few magazines" as an initial step in national advertising plans; about the advertising of MACLEAN'S MAGAZINE in all the MacLean Publishing Company's list of business and technical newspapers, about the influence of MACLEAN'S MAGAZINE on distributors.

But time and space forbid here and now a continuation of the MACLEAN story.
What is enough to be impressed is—

MACLEAN'S MAGAZINE

ISN'T THIS RATHER GOOD EVIDENCE THAT THE

Morse Silent Chain

IS DEPENDABLE?

THE above insert shows them operating the DIVING CONTROL in United States submarines. Could DEPENDABILITY be more essential anywhere? They also operate the STEERING APPARATUS and the PUMPING SYSTEM. Ever since the Government made comparative tests of all makes of silent chains (prior to the awarding of the contract for chains to operate the Panama Canal Emergency Gates), and discovered that MORSE SILENT CHAINS were of much higher tensile strength and much smoother running than any other make, Government specifications of all sorts are usually met only by "MORSE."

Why Don't You Profit by the Government's Experience?

MORSE CHAIN CO., Ithaca, N. Y.

Largest Manufacturers of Silent Chains in the World

BETTER THAN "GENUINE"

ATLANTIC ICE & COAL CORPORATION,
Athens, Ga.,
Dec. 19, 1916.

The Magnolia Metal Co.,
New York, N.Y.

Gentlemen:—

For your information wish to advise you I have recently used your Magnolia Metal on our large engine where I formerly used genuine babbitt, which cost just twice the price of Magnolia, and find that Magnolia is as good, if not better, and I will continue to use Magnolia babbitt as long as I can get it. I do not hesitate to recommend it to engineers, where a good metal is required.

Yours truly,
ATLANTIC ICE & COAL CORP.,
Francis Jackson, Supt.

Sales Offices in All Centres **Toronto, Ont.** Representatives Everywhere

"Hm! This belt's nice and pliable, George. How do you keep it that way?"
"With Cling-Suface, Uncle. I let it take up all it would hold. It's 15 years old."

"DID you wish to see me?"

The Superintendent came up and shook hands. "You're the fifth belt dressing man who's been in here this week. I'll tell you what I told the others: my belts are large enough, and are not slipping. I don't need CLING-SURFACE."

"That's fine!" said our salesman, "And how are they lasting?"

"Lasting? Great! I use an oil—put it on whenever they get dry—been using it all winter."

"Are you running any of them slack?"

"Well, not exactly. But they're not too tight, and they're big enough to carry the load—Taylor system, you know?"

"Yes. Say, did you ever look up Taylor's figures? You know he made a nine-year belt test at the Midvale Steel Company, from 1884 to 1893—three years before CLING-SURFACE was discovered. He found for one group of belts that the average cost per belt for cleaning, greasing, tightening and repairing was $12.23, of which greasing and cleaning alone was $4.24. That leaves about $8.00 per belt, or 65%, for tightening and repairing. How would it strike you, Mr. Hood, to just quit tightening belts altogether, cut out repairs, and save this 65%?"

"Do you mean—never take up a belt?"

"Not until the sides touch, yes."

"Can't be done!" the Superintendent exclaimed, "What's to prevent the slipping if it gets too loose?"

"The belt itself! Make your belts slip-PROOF. You can do it here with any belt you've got. Take this picture, for instance. Here's a 20" double-leather belt, doing 225 H.P., running over a mile a minute and operating a dynamo in an electric light plant. Almost every condition unfavorable, yet it hasn't been taken up in 11 years.

"The semi-liquid CLING-SURFACE has body, heaviness. Once in a belt it stays there, surrounds and preserves the fibres, and prevents drying out or cracking. It makes the belt mellow, pliable, elastic, and gives it weight instead of taking it away, whereas a thin oil makes your belt pliable but spongy.

"And it's a pure compound. We've sold it all over the world since 1896—and make it now so you can use it cold. It's guaranteed absolutely."

"Hm!" Mr. Hood was thinking hard—thinking about the scarcity of labor and the big Government contract the firm was going to get. "You say I won't have to take up my belts—that they'll run without slipping under full load, anywhere, and last longer?"

"Absolutely, Mr. Hood," said our salesman. "The Cling-Surface Company won't charge you a cent if you don't get these results. Shall we say 50 pounds on this understanding?

* * * * * * Thank you!

"Remember, use CLING-SURFACE and you won't need belt dressings."

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways.
W. C. McGHIE, Chairman of Board.
W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID,
Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D.,
Supt. Trades & Labour Branch

Canadian Association OF Stationary Engineers

"The objects and purposes of the Association shall be to promote by all lawful means the efficient operation of steam and electric power plants, and for the said purposes:

(a) To serve as a school of instruction for its members;

(b) To hold meetings for discussing theoretical and practical matters pertaining to its calling;

(c) To examine stationary engineers and firemen as to their proficiency, and to grant graded certificates of ability to its members, and to be a medium through which steam and electric users may be supplied with good and reliable engineers, and to grant relief to its members in cases of sickness and distress."

By joining one of the subordinate associations of the C.A.S.E. you will be greatly benefited. For full particulars write

The Heat in Your Steam Condensation

WHAT ARE YOUR DOING WITH IT?

A big *economy* or a big *waste?*
A big *saving* or a big *loss?*
Which is it in your plant?

Are you returning the condensation in your steam lines immediately back to the boilers as pure hot feed water—or are you allowing it to clog up your apparatus and slow down the operation of your plant?

The thousands of concerns—both large and small—who use the

Morehead Back to Boiler SYSTEM

turn the water of condensation right back to the boilers at from 270 to 312 Degrees F.—save from 8% to 10% in coal over the wasteful steam pump—and at the same time keep every inch of heating surface on their equipment working at the highest possible thermal efficiency.

If you are still depending upon steam pumps or other makeshifts for handling the condensation in your plant you can convert a big loss into a big saving by investigating the Morehead System at once. For complete particulars address

Dept. "A"
Woodstock, Ontario

SCANDINAVIA BELTING

SCANDINAVIA — FEDERAL ENGINEERING & SUPPLIES LIMITED — TORONTO — BELTING

For direct drives is a very satisfactory and economical belt. Can be used whether straight or crossed—on shifters in hot places—in oily places—in dusty places—anywhere that leather can be used. Its strength is remarkable.

We have a booklet that will help you rid yourself of much belting trouble. Sent free on request. Write for it to-day.

Federal Engineering Co.
LIMITED
172 John St., Toronto

UEHLING WASTE METER

COMBINED
CO_2 AND TEMPERATURE RECORDER

Record of CO_2 and stack temperature on one chart.

Does your fireman know how much fuel he is wasting? Do you know?

The Uehling CO_2 Recorder makes a complete 24 hr. record of your combustion efficiency and the CO_2 indicator at the Boiler Front holds the fireman responsible.

Get more Steam per pound of Coal and reduce your annual fuel consumption.

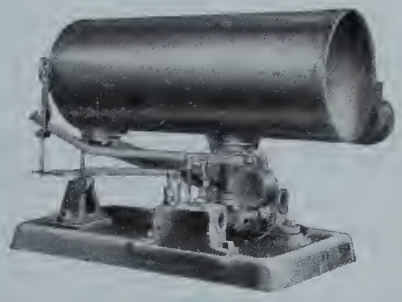
Let us know the number and size of your boilers and coal consumed per year, upon receipt of which information we will be glad to send you full particulars.

CO_2 Indicator for Boiler Front

Let us hear from you. We are pioneers in the manufacture of Indicators and Recorders for Power Plant purposes.

Send for our Bulletin No. 110.

Uehling Instrument Company
2008 Empire Building New York City



Paid For Itself in Thirty Days

The chances are that if a device does not prove its worth in thirty days there is little chance that it ever will. But this of this

"Detroit" Systems for Handling Condensation

have records of paying for themselves in thirty days.

Not only will a "Detroit" System pay for itself in a short time, but will continue to save hundreds of dollars a year right in your boiler room by saving fuel.

In your boiler room, as in many others, there is perhaps no adequate provision made to return the condensation.

Better let us send you "Watch Your Condensation."

Water Danger Alarm

What protection have you if you are away from your boiler and cannot see the register? What if the boiler at that time had too much or too little water? Serious results will follow if you happen to miss it.

With an Anderson Water Column this uncertainty is eliminated. When high water or low water mark is reached an alarm sounds **in time** to forestall the coming trouble.

The construction is amply shown in drawn illustration shown here. The material and workmanship is of the best. An inquiry to us will command our immediate attention and co-operation.

The V. D. Anderson Company

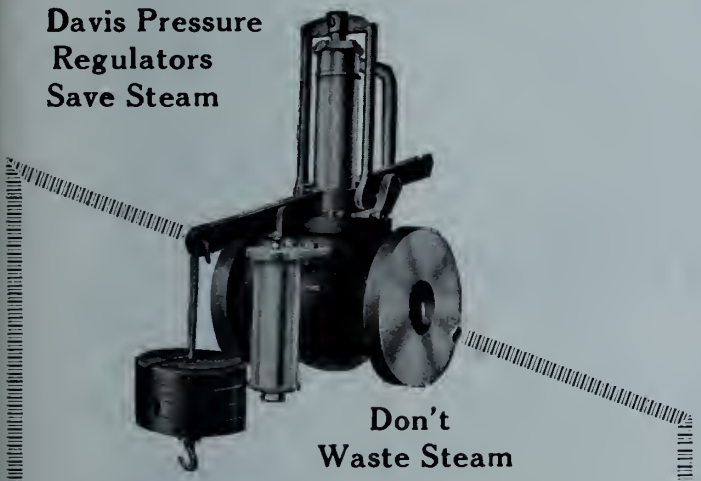
Davis Pressure Regulators Save Steam



Don't Waste Steam

You carry high boiler pressure for emergencies and peak loads, but are you sure this reserve is not slipping away? You know only too well the cost of coal —conserve it by keeping your steam pressure under full control with

DAVIS PRESSURE REGULATORS

Put these automatic valves to work wherever you can use less than boiler pressure. The cost is trifling and the saving big. Forty years on the market is enough to prove they are built right. Send for catalog. It will show you a way to cut costs.

G. M. DAVIS REGULATOR CO.
434 Milwaukee Avenue
Chicago - - - Illinois

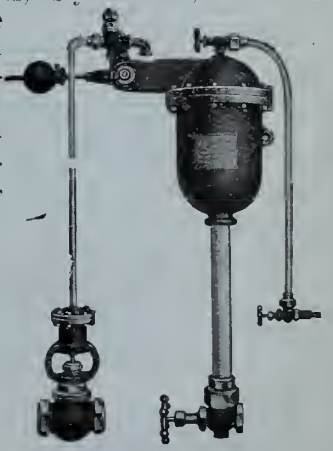
The VIGILANT REGULATOR is a genuine

Coal Saver

and the price of coal is high

The Vigilant Feed Water Regulator effects a saving in coal ranging from 3 to 17 per cent. This is a proven fact worthy of your attention in this period of increasing coal prices.

Boiler feed regulation is, as you know, a source of constant trouble and anxiety. You can overcome these difficulties entirely with the "Vigilant." On guard day and night.



Send for Engineers' Data Cards. Very useful.

GOOD LIGHTING

Adds To Efficiency and Reduces Accident Hazard

With the decreasing hours of bright daylight comes the problem of securing a satisfactory, efficient artificial lighting which will flood the engine room, boiler room, power house or factory with the nearest equivalent of sunlight.

The men working around the big machines, engines, dynamos, boilers, pumps, etc., are required to exert utmost care and accuracy in the performance of their labor. They need light —good light—bright, strong and clear,—flooding all corners of their room with equal efficiency.

LACO NITRO LAMP "THE LIGHT THAT GIVES MORE LIGHT"

puts the equivalent of soft, bright sunlight in your factory, mill or power plant. It gives you twenty-four hours of bright, soft, white light. It relieves eye-strain, increases accuracy, eliminates losses due to inadequate lighting, reduces accident and error hazard and makes your factory or mill cheerful, bright and agreeable for your men.

This wonderful new Laco Nitro Lamp reduces the current consumption. It is the latest development of the tungsten electric bulb. The tungsten filament in the Laco Nitro Lamp is suspended in a nitrogen gas-filled bulb—giving a clearer, whiter and greater light for a given amount of power than any other type lamp.

Inquire from your nearest dealer.

Plibrico Jointless Firebrick — Endorsed by some of the leading Engineers as the Greatest Furnace Lining Of Recent Times.

PLIBRICO—makes a solid one-piece lining without joints. Absolutely gas and air-tight. Saves its cost in fuel in a month or two—you will have a steady fire with less effort and less coal by using it.
PLIBRICO—is mixed ready for use, requires only half the time to install and does not require skilled labor. Any laborer who is at all familiar with the building line can use it. DOES NOT BREAK, CRACK OR SHELL OFF LIKE ORDINARY BRICK.
Can be used for front door arches, side walls, brick walls, combustion chamber and rear arches. Sets quickly—after a few hours with a low fire to drain out the moisture, you may fire up as usual. No special forms required.
Ideal for temporary repairs. Better order a barrel and have it ready for an emergency.

PLIBRICO BOND— A HIGH TEMPERATURE CEMENT FOR REPAIRS.

"PLIBRICO BOND" is a product which gives a perfect bond between fire-brick, and does not allow the fire to burn out the joints, as is the case where fire-clay is used. Prevents furnace walls from cracking and crumbling.
It's the most practical and logical high temperature mortar you can use. It's the ever-ready repair cement that you should have in case of emergency.

Advertising makes for a better product—

Not only does advertising create a good impression regarding the product advertised but it **makes for a better product.** There are added responsibility and written-printed claims to substantiate.

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

INGLIS BOILERS

There's an Inglis Boiler for Every Purpose

Built to Give Long and Economical Service

Inglis Boilers are made to stand the severest tests and give the best of all-round service.

Best of material, best of workmanship, and best of experience are behind their construction. They easily pass all government tests. For efficient and economical boiler room service in your power house, have the "Inglis" equipment installed. Satisfaction guaranteed.

Put your boiler room problems up to us and write for prices and specifications. We build boilers of all kinds for all purposes.

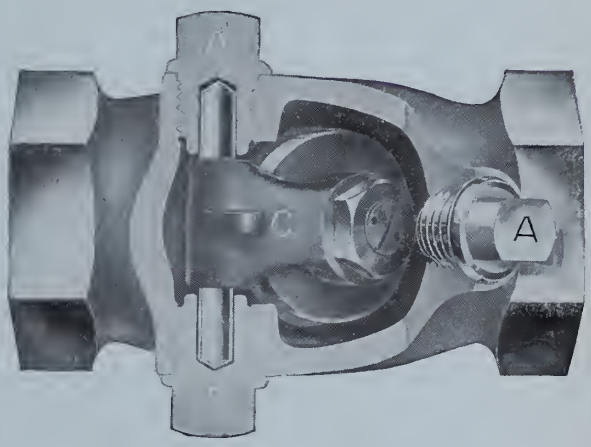
Registered For 200 Lbs. Steam Pressure



SECTIONAL VIEW

THIS IS THE SWING CHECK

THAT WILL SOLVE YOUR CHECK VALVE TROUBLES

"BUILT FOR SERVICE"

Note the correct angle at which the disc rests when closed. Prevents opening of same from pressure of condensed water in pipe, or from pipe line getting out of true. The body of the valve proper is not subject to wear from action of disc, as the hinge pin "C" bears on the two end plugs "A", and these parts can be renewed at very little cost. In some makes of valves the hinge "C" rides in a groove of the body proper and in case wear throws the disc out of line, the whole valve has to be replaced.

The double plug construction enables the valve, if installed in a wall pipe, to be taken apart without taking down the pipe line, as one plug is always accessible. The valve can be reground in a very few minutes, making same as good as new. The metal is of excellent quality and is distributed evenly and liberally throughout body and diaphragm to insure strength.

14 Jones Underfeed Stokers

Saved ½ the Cost of Installation

In fact, they saved over one-half the total cost. Installed in the plant of the Dominion Sugar Co., Limited, Kitchener, Ont., this was their performance in coal saving

In a Little Over Two Months

And by no means is the saving of coal the only benefit derived from Jones Automatic Underfeed Stokers. They'll save much of your boiler room labor cost as well. And no matter what the fluctuating boiler load, they'll provide steady steam pressure *always.* Moreover, they'll eliminate smoke nuisance once for all

We've a booklet picturing a few of our many Canadian installations. Mention your interest in saving coal, and we'll send a copy. We'll also send price information that will probably please you.

Jones Underfeed Stoker Company, Limited

National Trust Building, Toronto, Canada

CHEAPER COAL and NO CLINKERS

Imperfect combustion resulting from air shortage is the cause of clinkers. Enough air will add 25 per cent. more heat to the fuel gases and minimize clinker formation. Abundant air is provided by

ANTI-CLINKER SHELL BAR GRATES

Of their total surface 50 per cent. is air space. Therefore without clinkers forming they burn slack, coal or coke. They also burn wood. And whatever fuel used, maximum heat is obtained.

Anti-Clinker Shell Bar Grates can neither twist nor warp. By pressing lever they are turned to new burning surface, the coal is broken up and the fire left clean. Write us.

TIP-IT

Patent Welding Process makes it posible for you to obtain tools with carbon shank permanently united to cutting tip of high-speed steel. Save a good deal.

Copper Asbestos Boiler gaskets end all leaks in pipe lines. They are made of corrugated copper—the corrugations filled with pure asbestos cord.

Daniel's P.P.P. and Ebonite Packings for all pressures. Long tests by mechanical engineers proved that P.P.P. saves 75% or more friction losses. It automatically regulates bearings on rod to requirements.

Rids Boilers of Scale

A boiler scale remover better than the best you have ever used—not an ordinary compound. Every bit of scale goes for good—it can't even start to form—with Boico working. Boico will not foam, prime or carry over in the steam. And it is absolutely non-injurious to packings and valves.

Send for free trial supply.

Galt Sprinkler Stokers Applied to two 300 H.P. Water Tube Boilers. Since the Above Photograph was taken Additional Boilers of this Plant have been Equipped with Galt Stokers.

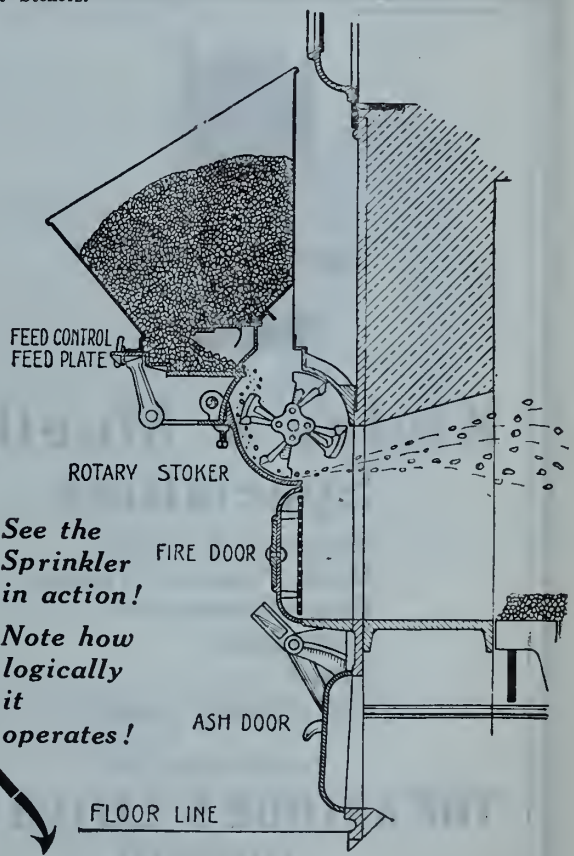
When Coal Costs So Much Why Waste It?

Don't you think you are burning too much fuel? Ask our mechanical engineer to visit your plant and talk over the matter with you. His service is at your command without charge and places you under no obligation whatever.

The Bureau of Mines, Washington, D.C., have just issued a report on exhaustive tests made by eminent engineering experts in the burning of fuel under power-plant boilers.

AND THEIR VERDICT WAS—

That the highest boiler efficiency on every test was always obtained with a level fire 3 to 4 inches thick, combined with frequent and light charges of fuel to the furnace, and the nearer the supply of coal approached a continuous feed the better were the results.



The Galt Sprinkler Stoker automatically feeds and uniformly spreads the fuel to the furnace in a light continuous stream and gives a perfectly level fire, 3 to 4 inches thick.

WHY put in another boiler

WHEN you can increase your present steaming capacity to 200 and in connection with stokers even 300% of the normal rating of the boilers without injury to the boilers by installing a

COPPUS TURBO BLOWER

You will have all the steam you want all the time. Hundreds of satisfied customers will attest to this. No drop in steam pressure when a heavy load comes on, and you can laugh at the weather man, as you can dispense with him for your draft. Besides, the blower will pay for itself in a short time, as it will burn cheaper fuel.

Cut out this Ad., put your name and address on the margin, and mail to us. Without further trouble you will get all the particulars.

500,000 H.P.

In boilers equipped with Coppus Turbo Blowers in four years. The Coppus has replaced a great many other blowers, but no other blower has ever replaced a Coppus.

Engineers Who Take Pride

in a smooth-running plant, in saving time, trouble, worry and money, are particular about details of equipment

IT'S attention to **details** that brings efficiency. Efficient engineers know this. They hate to worry the "Boss" with explanations of accidents, trouble, or new purchases. They see that equipment is **right.**

Take steam hose, for example. You use it a great deal. It plays a regular part in your daily task. If you are ambitious—anxious to win approval by saving trouble and worry—you will see that your steam hose is trouble-proof.

GOODYEAR STEAM HOSE

is Trouble-Proof, Lasting, Economical

Goodyear Steam Hose is hose you will find good to handle. Its outer cover of rubber is made to adhere firmly. It will neither blister nor crack.

And mark this! Many tests and experiments have Goodyear chemists made to produce an inner rubber tube that would defy the action of steam.

Their best efforts are embodied in Goodyear Steam Hose. The gnawing action of steam will not take the "life" out of this inner rubber tube. It stays active—resists hardening—keeps free from cracks.

The plies in Goodyear Steam Hose are built of strong duck. They are embedded in a grade of rubber that remains active, keeps the hose flexible, welds the fabric together.

Better be safe than sorry. Unless you are using Goodyear now, a hose purchase may bob up any day. Specify "Goodyear" for future equipment.

It will help you to know the service extended by Goodyear in solving hose problems. There's a Goodyear representative located in your territory. His experience and advice may help you.

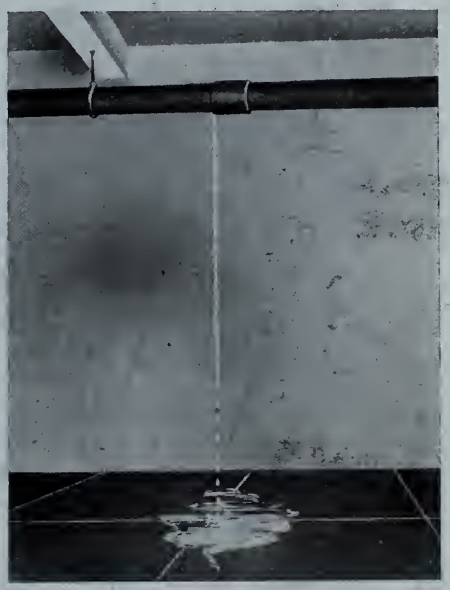
ICE MACHINERY SUPERIOR SINCE 1882

Canadian Representatives:
FRICK ICE & REFRIGERATING COMPANY, Montreal, Canada

You Would Not Allow This In Your Plant



If a brine line should develop a leaky joint, wouldn't you have it repaired as soon as possible? You would not let a loss like that continue very long. But how about the unseen loss of refrigeration from the brine and ammonia lines, coolers, tanks, etc.? Have you reduced it to the minimum, by insulating them with the proper thickness of

Nonpareil Cork Covering

For All Cold Pipes and Tanks

You cannot see it, of course, but a surprisingly large amount of refrigeration is lost from bare, cold pipes. For instance, 93 feet of 4-inch pipe, carrying brine at 15° F. with the surrounding air of 75° F. would lose one ton of refrigeration every twenty-four hours. The same would also be true for 120 feet of 3-inch, or 176 feet of 2-inch line. Even at the low cost of 50c per ton for refrigeration, this loss would amount to $180.00 per year. If, on the other hand, the lines were insulated with the proper thickness of Nonpareil Cork Covering, at least 80 per cent. could be eliminated—reduction of $144.00 per year.

Would it not be a good plan to check up the amount of bare cold piping in your plant, and then let us tell you how much refrigeration Nonpareil Cork Covering would save?

Full information upon request

Armstrong Cork & Insulation Company, Ltd. 504 McGill Building MONTREAL, QUE.

TORONTO November, 1917

The Economy of Business Paper Advertising

By H. E. CLELAND, NEW YORK

Awarded the Higham prize at the convention of Associated Advertising Clubs, at St. Louis, June, 1917. This prize is given annually to the one delivering the most constructive address in the fewest words.

ECONOMY is a many sided question and may mean anything up to the threshold of total abstinence. But Webster tagged it best when he said it means "a judicious expenditure of money."

War is shoving economy of this kind into the spotlight, thereby proving that war is not all battles, blood and what Sherman said it was. War has its good side. It has upset a centuries-old and centuries-rotten despotism. It has whipped British manufacturing methods into a state of high efficiency. It has waked up a snoring America.

In these conditions there's room for the advertising man, whether he be publisher, agent, salesman or user, who persists in dressing advertising in garments of glittering guff. It must be stripped to its effective self; made ready to fight, not to pose.

In brief, advertising must now line up with every other business and make every dollar spent for it a "judicious expenditure of money."

The business press of the country welcomes this return to the fundamentals, for with this attitude must come a full appreciation of the effective economy of business paper advertising.

Business paper advertising has never posed. It never has been nor will be surrounded by the pomp and circumstance of enormous circulation. It cannot hope to fly the banner of tremendous rates. The average cost per page is so low that it doesn't sound respectable.

In short, business paper advertising is not the bass drum of this band. It doesn't make the noise—but it carries the tune, clear and true.

We assert for it a very high efficiency per dollar of cost. And that, we believe, is the aim—and rightfully the aim—of every straight-thinking advertising man.

THE REASONS WHY

And these are the reasons why it is effective.

First, the editorial character of each paper limits the circulation to those men in an industry or trade who are responsible for results. These are the men who actually buy or recommend the buying of the machinery or merchandise advertised in the paper. Therefore, waste circulation practically does not exist and is in every event cut to the bone. Hence, at the very beginning we strike at effective advertising's greatest extravagance, waste circulation, and put in its place intensive circulation.

Second, the buying power per subscriber represents an infinitely greater sum than the buying power per subscriber of any other class of publication because each buyer purchases for business and not private consumption.

Third, the editorial contents of the paper are in harmony with the advertising pages. The first tells a man "how" and the second shows "what with." To borrow the simile of a colleague of mine, the whole paper may be regarded as an enormous advertisement with the editorial pages carrying the educational copy and the advertising pages representing the return coupon.

In a recent investigation as to the effectiveness of advertising run next to reading matter and advertising which was segregated, it was demonstrated that when the reading matter next to the advertisement was germane to the product advertised, then results from the advertising were far and away ahead of results when the reading matter was on a subject foreign to the product advertised.

This investigation was carried on in the general field, but I regard it as one of the best arguments for business paper advertising I have ever heard. In a sense, all advertising in a business paper is "next to reading."

Those three fundamental reasons form the backbone of effective economy in advertising and sum up thus:—

THE CONCLUSIONS

Business paper advertising is economical because it reaches—and the advertiser only pays for—a circulation of tremendous buying power which is continually being taught by the publication itself to want the products advertised.

The business of the busines papers is to exert a wise and wide influence upon the commercial and industrial development of the country.

We cannot surround them with flowers and furbelows, nor is it necessary to allure the non-technical, non-trade man with pictures of Gertie Coughdrop, "the film's flossiest flapper."

Our readers are not to be caught by any cheap expedients. And those editors and advertising writers who find it necessary to mount their untamed vocabularies, jab them a couple of times with their favorite adjectives, and ride off in a ribald revel of words, have no place in the modern business publication.

Business papers are not intended to amuse, are not intended for the tired business men. They touch men—and men only—on that side of their lives which occupies most of their wakeful hours. They instruct, lead, guide and help men to do things, to build things and to sell things. They are for the world's doers when they are in the midst of doing.

In one of Mark Sullivan's editorials in Collier's he says:—

"Progress is no monopoly of the cannon makers. In one issue of the 'Electrical World' we note that the Columbus (Ohio) Railway, Power & Light Company has set out to make its buildings safer. Fire escapes, standard doors, and other improvements have been added, along with a rigid system of inspection to prevent the accumulation of waste and grease, so that in three years fire risks and insurance rates have been cut nearly in half. In Johnston, S.C., F. M. Boyd, manager for the Carolina Public Service Company, has devised a new type of twenty-five foot pole with a twelve-foot mast-arm sticking out on the street side so as to keep the poles lined up on the curb, but get the wires away from the beautiful old elms and water oaks that are the glory of Johnston's highways. Anyone who has seen the ruin and multilation left by fanatical tree trimmers will appreciate Mr. Boyd's device. The Ohio Electric Light Association reports that its members have saved from three to five cents per ton on all coal handled at certain of their power houses by putting in an eight-hour day for firemen. This ought to interest the old-timers who think twelve hours' toil an inalienable right for engine-room workers. Those three items cover vital subjects and are only part of the grist in one issue of a live technical journal. That's how our United States goes along."

Those of you who know Collier's know that this comment is from an authority whose point of observation is a long way from the bull pen.

The C.P.R. Quebec Terminal Power House Equipment

Staff Article

While much of the pleasure and comfort of modern railroad traveling is due to the high standard of excellence attained in the construction and furnishing of rolling stock, the initial facilities accorded the traveler by insuring a proper start, have much to do with the degree of satisfaction resulting. Just how much mechanical equipment contributes to this end is set forth in the following article describing terminal power house equipment.

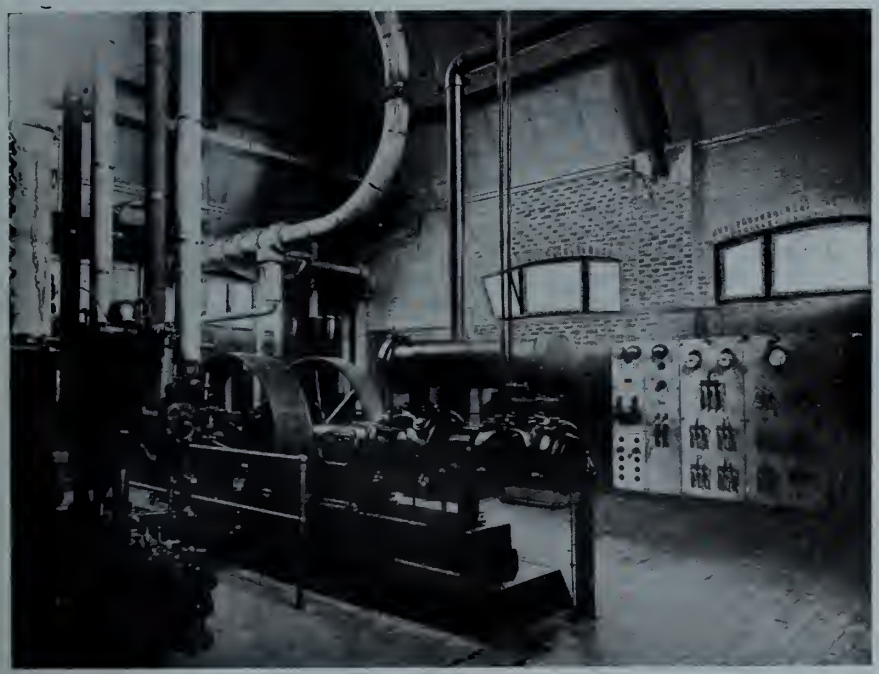
WHILE it is true that perfection is practically unattainable in any enterprise or industry, it must be admitted that a very high state of efficiency has been achieved in many lines of activity. In this respect it will be readily recognized that railroad travelling has become one of the greatest pleasures in which man can indulge. After a journey of many hours one can leave the train almost as fresh as when he entered it. Many things combine to make this result possible; proper ventilation the year round; ample heating in cold weather; upholstering that is thoroughly cleaned at all main terminals; modern toilet and dining accommodation; all these and others unite to improve the sanitary conditions that a few years ago were not among the advantages enjoyed at the present time. In keeping with the spirit of the times the Canadian Pacific Railway has always endeavored to anticipate the desires of the travelling public, and the latter have generously shown their appreciation of the company's efforts.

The recently completed power house in connection with the new station at Quebec exemplifies the modern nature of the facilities that are installed throughout the system for maintaining the high standard of efficiency that is so marked in every branch of the service. The building, which is designed on the French style of architecture, is constructed of bault limestone and citadel brick, with steep sloping, copper-covered roof. The building is almost square in shape, the dimensions being 48 by 66 feet, with the boiler room occupying about one-half the entire space.

AIR COMPRESSORS, FEED-WATER HEATERS AND HEATING SYSTEM GAUGES.

Boiler Capacity

Two twin Babcock & Wilcox, 150 horse-power boilers, equipped with superheaters, are installed; each set is provided with a separate header, that delivers steam through a 6-in. pipe to the 8-in. main, the 6-in. connection being fitted with a non-return valve and a gate valve. The steam required for the operation of the various engine room units is taken from the 8-in. main located about 20 feet from the floor. The boilers are equipped with Jones underfeed stokers, and the air for the combustion is supplied by a 5-ft. Sirocco blower, that is operated by a 6 x 6 in. vertical steam engine. Coal is delivered from the cars alongside the boiler room into bunkers adjacent to the firing end of the boiler.



GENERAL VIEW OF ENGINE ROOM.

The feed water pumps are of the Weir 12 x 6 in. duplex type and are located just to the left of the engine room entrance. These pumps take the water from the Cochran heater, into which all returns from the station and freight shed heating system are discharged, together with the exhaust from the engines and pumps; all water is metered as it passes through the heater. Both the 6-in. and 4-in. steam mains to the freight shed heating system and the 3-in. return have a total length of about 625 ft. The pressure required for heating the station is about 2 lbs., while that for the sheds is about 3 lbs. per sq. in. It might be mentioned that all eaves are equipped with steam jets to prevent freezing in cold weather. All reducing valves throughout are of Mason type. The station ends of all tracks are fitted with steam connections from the boilers for keeping stationary coaches properly heated during cold weather.

Compressor and Battery Plant

Facilities for the effective testing of air brakes on detached coaches is an important requirement in railroad ter-

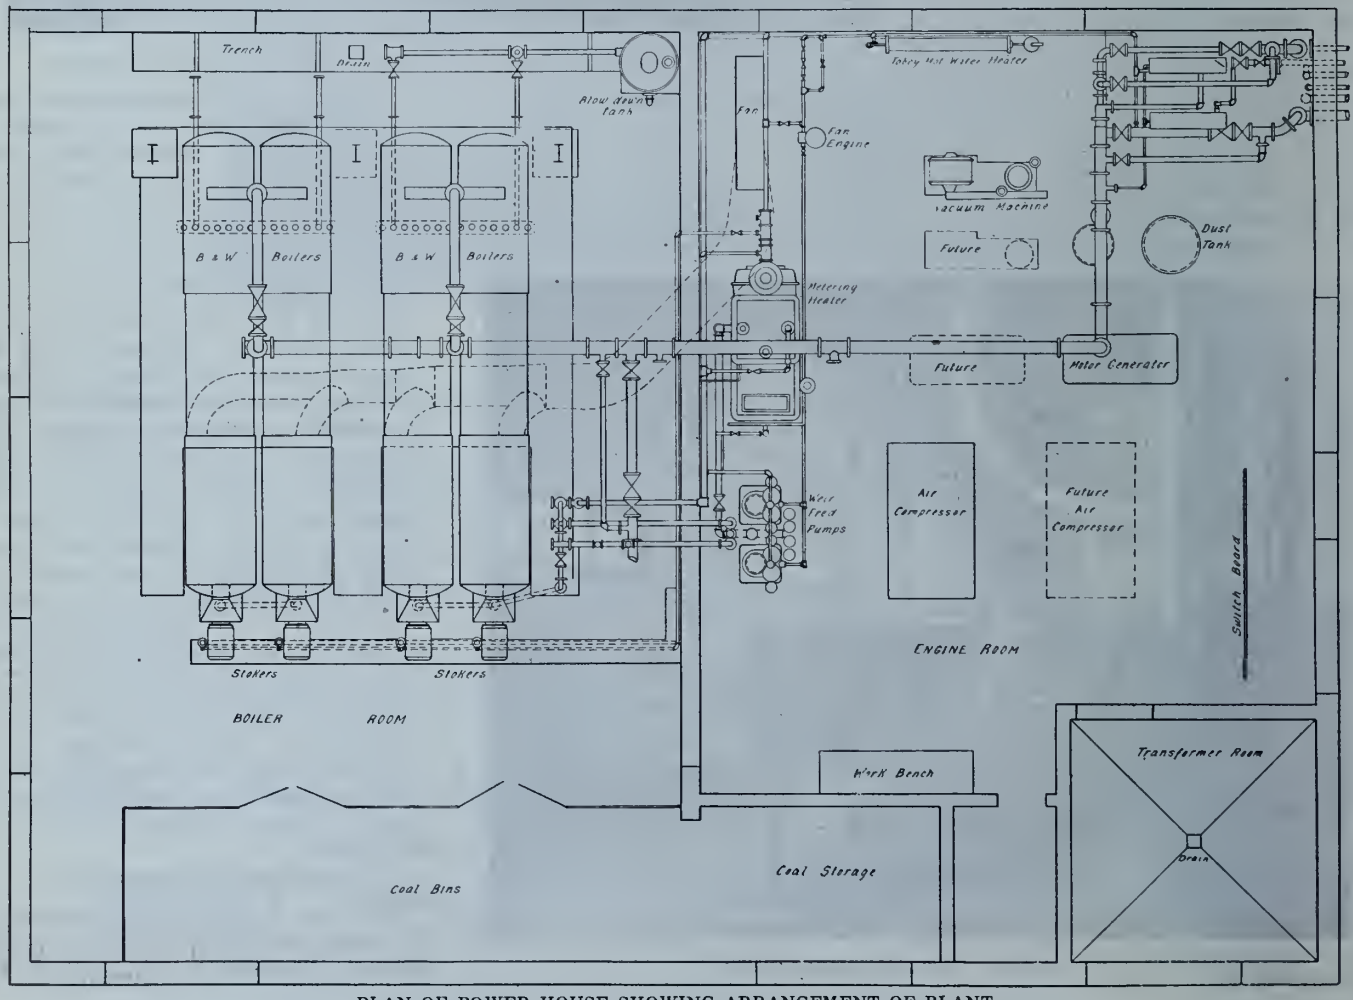
minals. For this purpose there is installed an Ingersoll-Rand 500 cu. ft. air compressor; this unit is belt-driven by a 75 h.p. Canadian General Electric motor. The compressor is fitted with an overload valve that closes the discharge when the desired pressure in the reservoir has been attained, permitting the machine to run light until the pressure again falls below a certain point. A special panel is located to the left of the main switchboard and is equipped with an automatically-controlled set of four magnets for regulating the speed of the motor when taking up the load; this is very necessary owing to the high compression under which the compressor is started. Pressure regulators are set on the wall adjoining the switchboard to control the starting and stopping of the machine. The air receiver is located just outside the building. As an auxiliary, in event of mishap to the large machine, a 9-in. Westinghouse locomotive type of air pump has also been installed, which has volume enough for all ordinary requirements. The entire passenger yard is piped for testing brakes on all cars.

For charging the batteries installed on the coaches for the electric lighting system a Canadian General Electric 15½ ampere, 550 volt, motor-generator set has been provided. This unit is equipped with automatic control by a set of magnets set at the desired voltage to avoid over-charging. At present only two tracks are available for supplying the batteries on the coaches, but should the necessity arise, facilities can be extended.

VACUUM CLEANING OUTFIT, MOTOR GENERATOR SET AND MAIN SWITCHBOARD.

An important requirement in passenger train service is the maintaining of the upholstery in the desired state of cleanliness, as an almost unavoidable feature in railroad operation is the accumulation of dirt and dust while the train is in transit. At this terminal the C. P. R. has installed a modern Sturtevant vacuum cleaning system for use in the coaches. The centrifugal suction fan is operated by means of a 7½ horsepower motor, and the apparatus is supplied with two receivers—one large tank outside for receiving the large particles and a smaller one forming part of the machine, into which the smaller dirt and dust is discharged. The entire passenger yard is fully equipped, so that cars in any location can be operated on conveniently.

With the exception of the vacuum machine, the engine room equipment is



PLAN OF POWER HOUSE SHOWING ARRANGEMENT OF PLANT.

BABCOCK & WILCOX BOILER INSTALLATION WITH UNDER-FEED STOKERS.

automatically operated, assuring continual service for yard operations, even in the absence of the power house engineer. The present building has been designed to accommodate sufficient machines to double the existing requirements, should future developments necessitate such increase of capacity.

SIBERIAN TRADE REQUIREMENTS IN OIL ENGINES AND MARINE MOTORS

L. D. WILGRESS, Canadian Trade Commissioner for Siberia, sends the following particulars from Omsk regarding trade in Siberia in oil engines and marine motors. It is hoped that these particulars will assist Canadian manufacturers of the products in question to determine the prospects for developing business with this market.

Trade in Engines

A considerable demand was created in Western Siberia before the war for oil engines designed for various farm uses, such as the operation of flour mills, threshing, the pumping of water, etc. Previously the demand in this branch of trade was chiefly for portable steam engines with colonial fireboxes, enlarged especially for burning wood. With the amount of wood available for fuel purposes, this was considered the engine most suitable for use in Siberia. The rise in the price of wood, the prevalence of alkaline water in certain districts and particularly the campaign conducted by Swedish and other manufacturers, gradually created a demand for oil engines, with the result that the number of portable steam engines sold each year remained stationary, while the trade in the former greatly increased. Lately the business in steam engines has been largely confined to dealers in power-threshing outfits. These have been chiefly of British and German manufacture, the largest sale being in sets with a nominal 10 horse-power, but an actual 36 horse-power.

Types of Oil Engine in Demand

The oil engines sold in Western Siberia previous to the war were chiefly of Swedish and Russian manufacture, supplemented by a limited import from Germany and Great Britain. These engines were either sold to co-operative societies for the operation of flour mills, creameries, etc., or to individual peasants for general farm purposes. For the operation of flour mills and similar heavy purposes, the most usual size required is from 32 to 40 horse-power. The largest demand, however, is for one-cylinder vertical motors of from 10 to 16 horse-power size, suitable for operating threshers, small flour mills and for other farm uses. During the summer the farmers use their engines for threshing grain and other purposes, while during the winter they grind the grain by operating small unit flour mills, using their oil engines for power. There is also a considerable sale of the smaller sizes of engines of from 4 to 8 horse-power, which are used for pumping water, operating threshers, etc. The tendency has been, however, for a greater number of the larger sizes of engines to be sold each year, since the economy of purchasing a somewhat larger engine is becoming recognized.

The fuel used for oil engines in Western Siberia is either kerosene or what is locally known as "naphtha." This latter is similar to what is sometimes referred to in America as crude oil and is practically kerosene before the benzine is extracted from it. Gasoline is too dear to permit of its use for fuel purposes in Siberia. Since the outbreak of the war the high cost of kerosene and naphtha has placed the owners of oil engines at a disadvantage.

The requirements of the market call for an engine which is above all things simple to operate. This is one of the objections held against certain engines of the North American type as compared with those manufactured in Sweden and Germany. There is also a prejudice among the Siberian peasants against the horizontal motor, it being held that the friction is greater than in engines of the vertical type. The accompanying illustration shows a 10 horse-power engine manufactured by a well-known German firm. This oil engine is of the type which has enjoyed the largest sale in this market. The retail price of this particular motor before the war was 1,800 roubles. A 5 horse-power engine manufactured by the same firm sold for 750 roubles. These prices may be taken as representative of the prices paid for oil engines in Western Siberia previous to the outbreak of the war.

Marine Motors

There should be an opening for the sale of Canadian marine motors in the Russian Far East. The development of the fishing industry of Eastern Siberia has led to an increased use of motor-propelled boats, while sailing vessels with auxiliary motor-power have proved to be the best suited for the trade along the coast where the population is very scattered. Motor-boats are also beginning to be used to a greater extent on the principal rivers of Siberia for purposes of communication and in connection with the fisheries. Motor-boating for pleasure is still in its infancy, although the sport appears to have gained a foothold in the principal towns. Motors of Swedish manufacture are chiefly to be seen, but it is reported that the sales of American motors are increasing in Eastern Siberia, where the conditions of competition are more favorable to Canadian and United States manufacturers. Kerosene is the principal fuel used, gasolene being too dear for general use. The type of marine motor required in Siberia is one of strong construction and simple design. All sizes are in demand varying according to the purposes for which the motors are to be used. The names of some of the principal dealers in Vladivostok may be obtained on application to the Department of Trade and Commerce, Ottawa.

TO PROVIDE POWER FOR MUNITION WORK

SOME improvement in the power situation in Ontario is expected to follow the appointment of Sir Henry L. Drayton as "controller of the production and distribution of electrical energy by companies generating or distributing electrical energy in the Province of Ontario."

His duties as defined in the order-in-Council will be "to determine preferences and priorities in the supply of such electrical energy to the end that a sufficient supply shall be furnished to factories and users engaged, directly or indirectly, in munition work or work for any of the allied Governments, and also

for municipal and public utility requirements."

As much of the electricity now exported from Canada to the United States is used in connection with the war requirements of the two countries and their allies, the British Ambassador at Washington will be asked to arrange for a conference between Sir Henry Drayton and the proper authorities in the United States with a view to insuring co-operation between the two countries in the generation and utilization of electric energy on both sides of the international boundary to the end that the maximum efficiency may be obtained.

Sir Henry Drayton's appointment follows his investigation of a serious power shortage in Ontario, disclosed to the Government by the Hydro-Electric Power Commission. Sir Henry was appointed a Royal Commissioner to make an enquiry into the extent to which electricity was exported by the generating companies at Niagara Falls, and the extent of the demand in Ontario. His report was considered by a sub-committee of the Cabinet and was discussed at a conference between the committee, Sir Adam Beck and representatives of the power companies. At the conference the basis of an order-in-council was agreed upon. That order recognized the desirability of maintaining the suppply of electricity for munition plants on both sides of the international boundry, some of which were complaining of shortages of motive power. It also recognized the necessity of providing for the demand from municipal utilities. The order will apply to the Canadian Niagara Power Co., the Electrical Development Co., and also to the Ontario Power Co. which, although acquired by the Hydro-Electric Power Commission, still retains its corporate entity.

Sir Henry was authorized by his Commission to report upon the status rights and obligations of the companies operating at Niagara Falls; the amount of power available for distribution by those companies at Niagara Falls; the extent of the demand for power in Canada; the amount of power in the past exported by the companies and the present demands of the United States customers. He finds that the Ontario Power Company, recently acquired by the Hydro-Electric Power Commission of Ontario was authorized to export power to the United States, subject to a requirement to retain one-half of the electricity, it generated, for sale in Canada at prices not to exceed those charged to customers in the United States.

NEW ELECTRIC LOCOMOTIVE

THE accompanying cut illustrates a type of electric locomotive recently built by the Montreal Tramways Company, for operation on various sections of their system where heavy haulage is often necessary. The total weight is approximately 85,000 lbs., and the drawbar pull is upwards of 25 loaded freight cars. A feature of the locomotive is the method of obtaining the desired weight; the steel framing of the platform, consisting of I beams and channels, has an area of about 246 square feet and a depth or thickness of 12 inches, the intervening space being filled with solid concrete, giving a weight in the frame alone of nearly 35,000 lbs. Tractive power is obtained by four 200 horse-power motors, two of which are installed on each truck. The electric equipment is located in one of the apartments adjoining the central operating cab, while the other contains the air pumps and other pneumatic appliances. The sand is forced to the rails by means of small injectors operated by compressed air. Every facility has been provided for the convenience of the engineer or operator. The general dimensions are as follows: Over-all length at drawbar connections, 31 ft. 8 in.; length of car body, 29 ft.; size of cabin, 9 ft. long by 7 ft. 4 in. wide, with a height from the floor of 7 ft. 7 in. The wheel base is 21 ft. 6 in., the centres of the trucks being 15 ft. apart.

ELECTRIC LOCOMOTIVE BUILT BY MONTREAL TRAMWAYS CO. FOR STREET RAILWAY WORK. IT WEIGHS 85,000 LBS., AND HAULS 25 LOADED FREIGHT CARS.

IRON WEAPONS OF THE AZTECS

WHEN Cortez had completed the conquest of Mexico, the Spaniards, among a great many other peculiar and extraordinary observations which they made in that remarkable country, were particularly struck and puzzled by one fact.

They noticed that the Aztecs possessed certain implements, such as knives, daggers, etc., made of iron, but it seemed that only the most distinguished of the natives possessed such, that iron was a great rarity and was prized higher than gold. At first the Spaniards believed that the Aztecs extracted the metal in some crude fashion from its ore, which abounds in many parts of the country, but they soon ascertained that this was not the case. They found that not a single smelting furnace existed in the empire, and their surprise was not small when they learned that the Aztecs were totally unacquainted with any method of extracting the iron from the ore, which, indeed, they had never suspected of any kinship with the highly valued metal.

The question whence the Aztecs had procured the little iron they possessed became a perplexing problem to the Spaniards, which they were never able to solve. The natives do not seem to have enlightened them much on the subject, for when asked they mysteriously pointed to the sky, and indicated that they obtained their iron from the regions above. Such assertions, no doubt, the Spaniards received with an incredulous smile, and they concluded that the Aztecs procured it by way of traffic from some other, perhaps more civilized, nation which they suspected to exist and kept looking for north and south for more than a hundred years.

It was left to modern science to unravel the mystery. The Aztecs were quite correct; the iron of which they had made their implements was not fashioned from materials of this terrestrial globe, but had come to them from the unknown regions of space. Their iron was, in fact, of meteoric origin, like that of the Mayas of Yucatan, and the Incas of Peru, of which many weapons are still preserved for collections.—Hensoldt.

FOR the protection of ironwork paint is generally used and provided that rusting has not commenced a paint composed of four parts of red lead, one part white lead ground in oil and at least five years old and sufficient raw linseed oil of good quality will be found very efficient if used when freshly made. No driers are needed, as the red lead is a very good oxidising agent, but the paint takes several days to dry and harden. For ironwork red oxide of iron also makes a good paint if no driers are used and the oil is good, but if driers are used the paint soon fails when exposed.

Comparison of Working Costs of Principal Prime Movers*--I

By Oswald Wans

High thermal efficiency does not necessarily imply commercial superiority. Available data are seldom complete and render difficult the justification of claims and working costs advanced by advocates of respective prime movers. The engine of lower thermal efficiency may, therefore, under certain conditions, be the sounder proposition commercially.

THE problem of economical power is one that must repeatedly present itself to those responsible for the welfare of industrial concerns, or indeed to any one upon whom falls the onus to provide power for whatever purpose. Yet the available data are seldom complete, and are frequently misleading. The claims and working costs advanced in favor of the several prime movers are often conflicting and difficult to reconcile with fact. It is not suggested that a lack of good faith is responsible, as an analysis of such estimated costs generally reveals the fact that the explanation is to be sought in the too limited basis upon which the costs have been founded. The condition that a certain type of engine possesses an exceptionally high thermal efficiency does not necessarily establish its commercial superiority. On the contrary, an engine of lower thermal efficiency may, under favorable conditions, be a sounder proposition from the commercial standpoint, and this in practice is the ultimate criterion of the engine's worth.

Working costs based mainly upon the low rate of fuel consumption are practically useless, and although the statement may be termed obvious, nevertheless, not infrequently one finds that the capital charges are either inadequately covered or entirely ignored. One may allege, without feeling, that the advocates of internal-combustion engines have been the greatest offenders in these respects, but it must be acknowledged that nowadays the undertakings of manufacturers generally are based upon broader lines, due doubtless to the accumulated data consequent upon a more extended experience.

The object of this paper is to give data that will be of service in estimating capital expenditures and working costs, and in establishing the relative commercial value of the principal prime movers. For this purpose typical examples of the following prime movers will be considered:

Suction-gas engines and plants burning anthracite, coke, and wood refuse.

Gas engines using town gas.

Oil engines of the solid injection high-compression type.

Diesel engines.

Steam engines.

The scope of the paper includes units up to a working load of 500 b.h.p., a power range embracing the engines for which there is by far the greatest demand. For higher powers two or more units can be used sometimes with advantage, for such installations possess a considerable power flexibility, in that the units may be cut out or put into service to suit the load requirements. This facility largely obviates the disadvantages of underloading, particularly valuable in the case of an internal-combustion engine, and offers a further advantage in the event of a break-down of one unit, for a complete stoppage of work may be prevented. In a multi-unit installation the expenditure and working costs may be taken as proportional to the number of units.

It is desirable to confine the present paper to the power units indicated, as the factors governing the costs of the larger installations are distinct, for example, the possibility of using bituminous coal with a recovery plant, live and exhaust steam tubines, etc., should be considered, thus introducing another set of conditions. It is perhaps hardly necessary to state that working costs, to be of commercial value, must contain the charges due to capital expenditure, depreciation, etc., as well as those arising from the direct running expenses. Further, the latter should be founded upon "everyday" performances; the results of "kid-glove" tests should be carefully avoided.

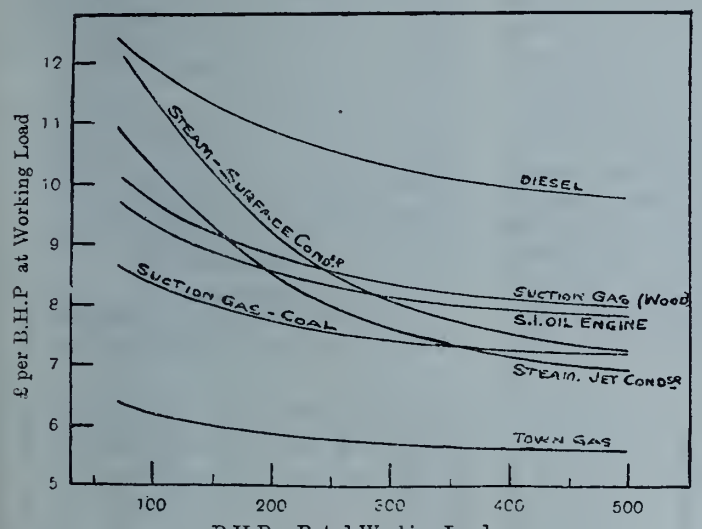


FIG. 1.—EXPENDITURE CURVES.

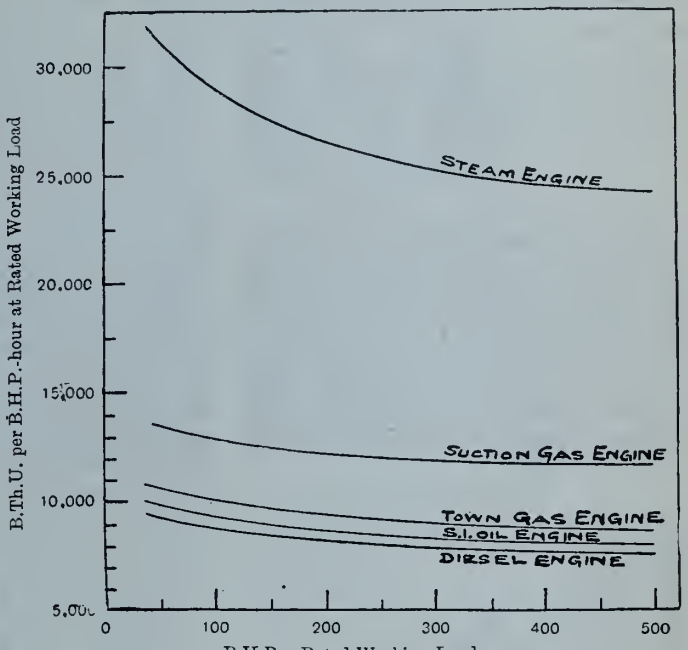

FIG. 2.—FUEL CONSUMPTION CURVES.

The items constituting the total working cost are:

- **Capital Charges:**
  - Depreciation.
  - Insurance.
  - Interest upon capital expenditure.
- **Running Charges:**
  - Cost of fuel.
  - " " lubricating oil.
  - " " water supply.
  - " " sundry stores.
  - " " labor.
  - " " repairs.

(Total working cost)

It is necessary to determine firstly the capital expenditure and this factor therefore will be dealt with at once and

*Read before the Institution of Mechanical Engineers, London, Oct. 19, 1917.

the remaining charges in the order tabulated. The charges arising from rent and taxes must be considered in addition, but owing to the wide variation in their amounts, it is not possible to make allowance here. They can be determined with accuracy only after a full investigation of the local conditions.

Capital Expenditure

The capital expenditure should cover the total cost of the completed installation in working order. The following list gives the items included in the expenditure curves, Fig. 1.

Installation	Items included in Expenditure
Suction gas engine. Town gas engine. Solid injection oil engine. Diesel engine.	Industrial engine, pulley, foundation bolts, compressed air starter with receiver and connections, exhaust pipe and silencer, barring gear, cooling tower, tanks, water circulating pipes and pump, foundation erection.
Additional for suction gas engine.	Producer,, cleaning plant and charging platform, air and gass piping, producer foundation and bolts, erection.
Additional for town gas engine.	Gas bag, connections, and air piping.
Additional for solid injection oil engine and Diesel engine.	Fuel tanks and piping.
Steam engine.	Industrial jet and surface condensing super-heated steam engines, barring gear, foundation and bolts, steam, exhaust and feed piping, boiler, seatings and flues, super-heater, feedwater heater and pump, steel chimney, economiser for 150 b.h.p. and upwards, erection.

It will be observed that buildings and flooring have not been included. These exemptions are made, as their cost varies widely, being largely dependent upon the taste of the purchaser, and may, therefore, range from a bare galvanized structure to a substantial stone or brick building. Furthermore, existing buildings are frequently used with more or less modification.

The cost of the buildings for internal-combustion engines would be less than for a steam plant, and this applies equally to suction-gas engines, for the producer and cleaning plant do not require a covering, whereas some form of protection is necessary for a boiler. A well-equipped engine-house should possess a crane, but the cost of this item is dependent to a certain extent upon the proportions of the engine-house, and has consequently not been taken into consideration, but its cost would not be materially different for the several types of engines. Cooling towers have been included in all cases, with the exception of the small gas and oil engines of about 50 b.h.p., as the more usual practice is to employ cooling tanks suitable for thermo-syphon circulation.

When deciding the size of the engine, it is necessary to consider its overload capacity, for this factor greatly affects the capital expenditure, the reliability, and the fuel economy. It may be remarked in passing that much of the trouble at times experienced with internal-combustion engines is solely due to excessive overloading. That gas and oil engines should have a large power margin is an essential of reliability and cannot be too strongly emphasized. The effect of the overload capacity upon the economy of an installation is dealt with later, and for the present merely its influence upon the capital expenditure will be examined. The maximum overload that may be depended upon varies considerably with the type of engine, thus:

Steam engine.....35% above rated working load
Solid injection oil engine .....15% above rated working load
Diesel engine.....15% above rated working load
Gas engine.....10% above rated working load

The larger overload carried by a steam engine is a characteristic of considerable value in the handling of fluctuating and peak loads. Moreover, this advantage is attained without impairing the fuel economy at the working load. Unfortunately this feature is not possessed by an internal-combustion engine. An overload of 35 per cent. may be carried, but only at the expense of the fuel economy at the mean working load, which in the case of a gas engine would be about 18½ per cent. below the rated working load.

The degree of importance to be attached to the overhead capacity of an engine can be decided only after full consideration of the duty required, but for the purposes of comparison it is necessary that similar load conditions are considered for all installations. A common maximum load of 35 per cent. above the mean working load consequently has been assumed, and the effect upon the capital expenditure is illustrated by the following table:

Plant	Rated Working	Rated Max.	Necessary Inc. in Rated Max. Load to give 35 per cent. overload
	B.H.P.	B.H.P.	
Steam engine.....	100	135	Nil
Oil engine.....	100	115	17½ per cent.
Diesel engine....	100	115	17½ per cent.
Gas engine.....	100	110	23 per cent.

For a mean working load of 100 b.h.p. and 135 b.h.p. maximum load it will be seen from the fourth column that a larger internal-combustion engine is required than is indicated by the rated working load. For example, the gas engine must have a maximum load some 23 per cent. greater than the rated maximum load usual for a 100 b.h.p. rated working load engine requiring, it follows, a larger engine and outlay than appears at first sight to be necessary.

The expenditure curves, Fig. 1 (page 309), give the total cost per b.h.p. at the rated working load, and from which it will be seen that the cost of suction-gas engine and plant of 100 to 110 b.h.p. is £8.3×100 = £830 as against £8.1×123 = £997 for a 100 to 135 b.h. engine. That is to say, the cost of the gas engine is increased by approximately 20 per cent. in order that it may perform a duty equivalent to a steam engine of 100 b.h.p. rated working load. This example serves to illustrate how necessary it is when comparing capital expenditures to place the comparison on "all fours" as regards power capacity.

The expenditure curves are based upon the costs of horizontal engines, excepting Diesel engines, but would not be greatly different for the vertical type. Generally speaking, vertical engines cost more per horse-power, but a saving is effected in the cost of the foundations.

Depreciation

A divergence of opinion appears to exist as to the annual charge that should be made to cover depreciation. The seller naturally wishes to place as favorable a complexion as possible upon the engine in which he is particularly interested, and it is to be feared that this

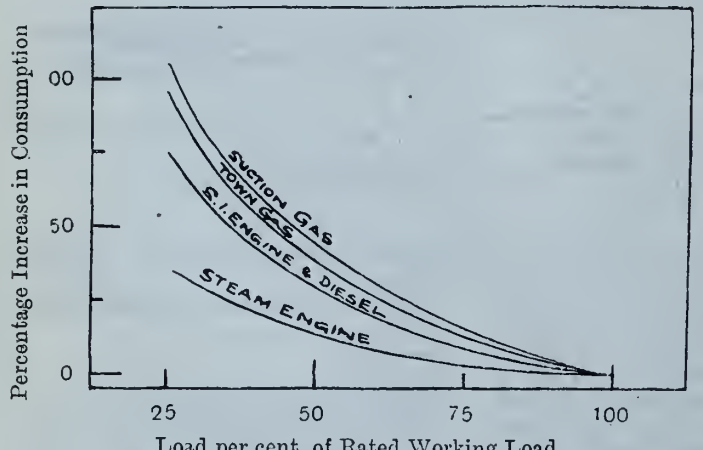

FIG. 3. CONSUMPTION AND LOAD CURVES.

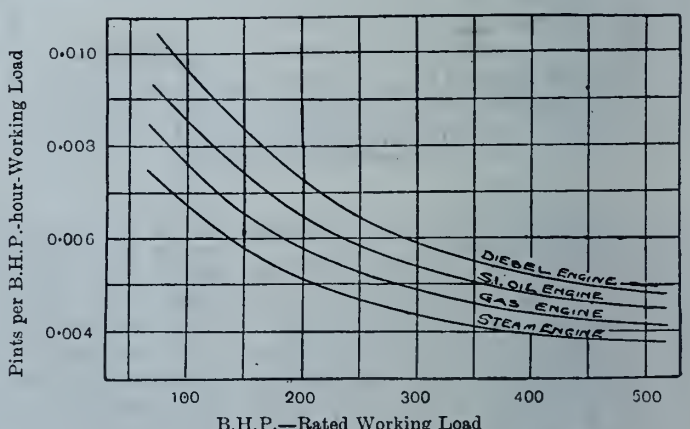

FIG. 4. LUBRICATING OIL CONSUMPTION CURVES.

desire tends to under- rather than over-estimation of the charges under this heading. Generally speaking, the estimated costs of steam installations show a greater uniformity and liberality in this respect than is usual with internal-combustion engines. As an example of

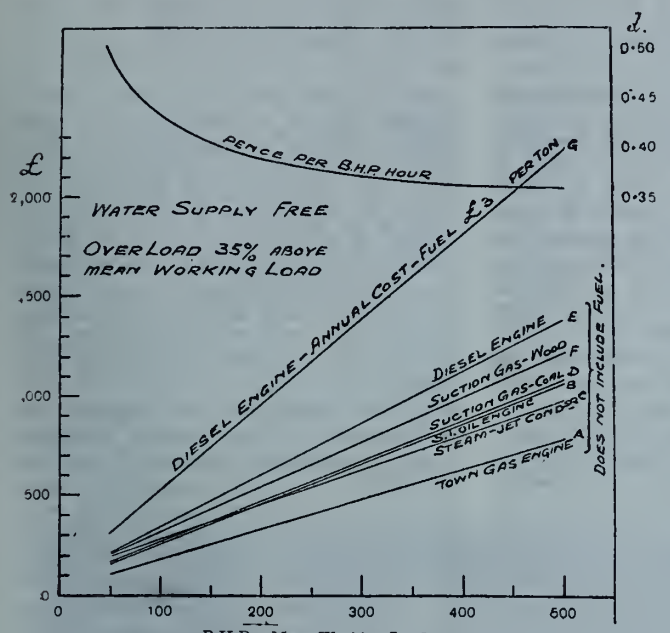

FIG. 5. WORKING COST CURVES.

originally installed. Yet it is surprising how often one finds an antiquated engine struggling along with its load, and positively eating money that could be saved by substituting a modern plant. The depreciation of 5 per cent. referred to above corresponds to a life of well over fifty

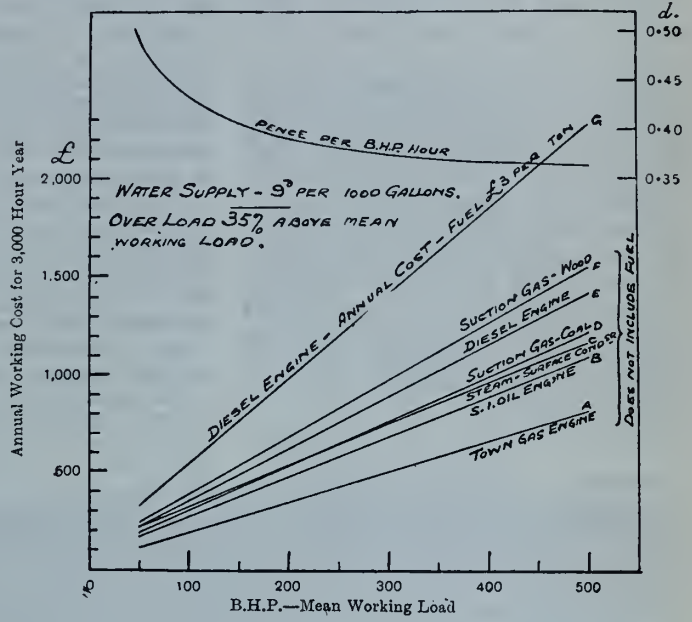

FIG. 6. WORKING COST CURVES.

the low rate for depreciation for the latter, the not uncommon charge of 5 per cent. may be cited. A little reflection should show how inadequate a provision this affords. It will be well to explain briefly what is here implied by the term depreciation. The depreciation charge is considered as the annual amount that should be written off the capital expenditure to cover the deteriorating value of the plant as regards obsolescence. This definition does not agree with general usage, inasmuch as wear and tear are not included.

In the author's opinion this departure is justified because:

(1) Developments are nowadays so rapid that there is an increasing tendency for a power plant to become economically obsolete before it is worn out.

(2) The allowance made for repairs should be sufficient, in a modern engine, to cover wear and tear during its economical life whilst serious breakages should be covered by insurance.

Viewed from these standpoints, it follows that the depreciation charge is solely dependent upon the anticipated economical life of the installation. In other words, it is not a matter of how many years an engine may run, but for what period it can be reasonably expected to maintain its economical superiority over competing prime movers irrespective of type. Immediately this superiority is lost, the commercial value of the installation, as a source of power, falls and the advisability of replacing it by an up-to-date plant should be considered.

It is false economy to keep a plant in service merely because it continues to perform the duty for which it was or-

years, if based upon the diminished value and allowing a high scrap value or about twenty years if taken in equal annual instalments. In either case the anticipated life is obviously excessive. The determination of this period must, in the nature of things, be somewhat prophetic, nevertheless the past, to a great extent, is an index to the future, and it may be inferred that an internal-combustion engine before the expiry of twenty years' service would be an extravagant consumer of fuel, and in a generally worn-out condition; indeed, this would be equally true of a steam installation.

The depreciation rate should spread the expenditure burden over a reasonable number of years, and permit in good time of the removal of the power plant in favor of a more modern type, should the developments in later-day practice render the running costs comparatively high. It is considered that a uniform annual rate of 8 per cent., equivalent to twelve and a half years' service, fulfils these conditions, and that this rate should apply to all the prime movers under consideration, seeing that the commercial life is dependent upon the best practice, irrespective of the type of engine. The amount written off annually is, therefore, 8 per cent. of the total expenditure given by the curves, Fig. 1 (page 4).

It should be noted that this uniform rate is intended to apply to cases in which the several prime movers under consideration are applicable and, therefore, in competition. The competitive factor applies to the large majority of installations, but there may be instances in which the working conditions render especially suitable a particular type of prime mover, thus eliminating this factor and thereby deferring the probable date at which the plant may be considered obsolescent.

Insurance and Interest

The cost of insuring an installation is a small item and varies somewhat with the power unit and the insuring company. The insurance premium for engines usually covers breakage, but not wear and tear, and this fact should not be lost sight of when fixing the annual reservation for repairs. The premiums range from about one-eighth per cent. of the cost in the case of boilers to about 3 per cent. for Diesel engines. The charges under this heading are therefore comparatively small, whereas the accruing advantages are self-evident. The rate of interest upon the capital expenditure has been taken as 5 per cent. in the working costs, curves Fig. 5 and 6.

Cost of Fuel

As already stated, estimated working costs, founded upon the fuel consumption possible at the most economical load, are of little value. Everyday figures only should be considered, and failure in this respect is frequently the cause of erroneous estimates. In practice the engine seldom runs at the rated working load, having to cope alternatively with loads that may be temporarily greatly in excess and at other times considerably less. These practical conditions have a marked bearing upon the working costs, and particularly so in the case of an internal combustion engine.

The accompanying curves, Fig. 2 (page 10), show the average consumptions in B.Th.U. per b.h.p. hour at the rated working load. These values, however, hold good only when these loads are carried continuously, and the extent to which modification is necessary to suit practical conditions is contingent upon the load factor and the peak loads to be

handled. These factors may vary widely, consequently each case must be considered upon its merits, but to effect a comparison a common overload of 35 per cent. will be assumed again. This condition necessitates the underloading of all the installations with the exception of the steam plant, that is to say, the mean working load will be below the rated working load to an extent dependent upon the maximum load capacity of the unit

This underloading increases the consumption, and the curves, Fig. 3, show the average percentage increase for a given decrease in load below the rated working load.

These curves clearly indicate the importance of the correct determination of the load factor, and the absolute necessity to consider similar load conditions in order that a true comparison may be made. The following table shows the increase in full consumption due to the underloading necessitated by an overload of 35 per cent:

Installation.	Percentage of mean working load below rated working load	Increase in consumption due to underloading from Fig. 3
Steam engine	Nil	Nil
Diesel engine	14.5	2.5
Oil engine	14.5	2.5
Suction gas engine...	18.5	12.0
Town gas engine.....	18.5	8.0

A farther allowance must be made for stand-by losses, which will depend upon the frequency and length of the stoppages. This loss of course applies only to suction-gas and steam installations, and the amount may vary considerably according to the care exercised. The following values, expressed as a percentage of the fuel consumption at the rated working load for a working week of 60 hours, have been included in the working costs, surves, Fig. 5 and 6.

	per cent.
Suction-gas installations, anthracite	8
Suction-gas installations, wood	6
Steam installations	15

In cases where the plant runs continuously throughout the week, the losses would be considerably less and would be about one-third, assuming that the boiler or producer fires are kept alight over the week-end.

THE MARCH OF PROGRESS

By C. I.

THE development of any particular branch of industry generally divides itself into three separate parts, which are sufficiently well-defined to enable the stages to be marked with exactitude. The first stage is that in which the process of trial and error predominates. The machine or engine produced is the product of experience. Continued observation in working, alteration of detail and rearrangement of elements constitute the methods by which a degree of perfection is obtained. So-called theoretical considerations play no part in this stage of development, the instinct or experience of the designer or operator being the deciding factor in all changes. In the second stage, the whole subject is minutely examined from a purely technical standpoint, and the reasons which underlie the various peculiarities in construction or operations are critically scrutinized so that some rational basis for future work may be arrived at. In this stage of development the product of experience will be found to be developing on wrong lines, and in defiance of certain truths which can be scientifically demonstrated. Or it may be that these truths are ascertained for the first time as a result of these investigations. The third stage of development is that in which the work of the pure scientist is turned to practical account, and in which designs and processes are modified to bring them into agreement with the results of scientific investigation. It is in this third stage that the great competitive race is run, and where firms and individuals who refuse to be guided by the most up-to-date scientific factors must come to grief.

There are many fields of labor in which the first machines are based on exact scientific facts and where, therefore, there are but two chief stages of development, but on closer investigation it will be found that in the thousand-and-one different branches which constitute one field of labor the three stages of progress are continually taking place. Thus, in the realm of machine tools, the first machine produced was one that would stand up to its work and give fair results in accuracy and quantity of production. Then when high-speed steel forced an investigation of the question of cutting power, and the forces at work during cutting, it was found possible to improve the design of the machines, increase speeds and also production. As the late Professor Nicholson once wrote: "The necessity for any serious application of theory or calculation in the design of machine tools was probably never felt until the universal adoption of high-speed steels. which rendered the reconsideration of the kinematical and dynamical principles governing design a matter of careful and of vital importance. A careful study of machine tool design from the theoretical side can be of substantial assistance to the successful designs. A complete knowledge of the forces operative, and the power required in performing a given piece of work, and of the most economical rates of cutting and feeding, taking into account all the factors which contribute to the total cost, must certainly be obtained and made use of, if the design is to stand absolutely secure in subsequent successful and useful employment."

Steam Generator Developments

In steam generator practice, the use of big flues and slow speeds of gases has been used so long, so as to allow a long period of contact of gas and plate, that it seemed as though this practice must be based on correct scientific facts. Many forms of spiral retarders were devised to increase this time of contact, and gave good results, but probably not for the reasons conceived by the inventors. Most probably for the very opposite reasons which the investigation revealed, namely, that the rate of heat transmission increased with the increase of gas speed, and that what was required was not a large volume of gas having a small surface area of contact with plate and a large control core which transmitted heat to the plate only by radiation, but a large volume of gas broken up into small streams drawn at very high speeds over the metal so as to yield all its heat by convection and do away with a slowly moving film in contact with the plate which acted as a heat insulator. The spiral and other retarders inserted in fire tubes had this effect in part, for they split up the gases and prevented the formation of a central core of gas, giving off heat by radiation only. So far theory has not found much practical application, but prejudice will be broken. The Lancashire type of boilers has advantages, and men are naturally reluctant to alter such an old friend; similarly in other fields. In agriculture, the farmer's idea of the action of his manure has been critically examined and found to be less promising than the new theories based on the action of nitrifying bacteria, with the result that new products, such as bacterized peat, are finding their way into service. So in all branches, including sewage treatment and water filtration, steam turbine engineering and air pump construction, the results of the second stage of the march of progress are always being brought forward for attention.

The necessity, therefore, for a thorough grounding in the theoretical side of the subject of one's life work, and the great value of a technical scientific training for the evolution of new inventions of merit, is one of the facts that these present days of the world's history are making increasingly evident.

PORTLAND cement, a constantly growing necessity, was first made in England in 1824. The name is taken from the resemblance of the mortar to the oolitic limestone of Portland Island, in the English Channel. The industry was later taken up in Germany. In both countries it grew enormously, and at the beginning of the present war the output in Germany amounted to 20,000,000 barrels annually, and that of England about half as much. Portland cement was first made in the United States at Coplay, Pa., in 1878, and since then works have been established in nearly every State in the Union. The growth of the industry is perhaps the most marvellous thing in the whole industrial development of this country. No farther back than 1894 the product was small.

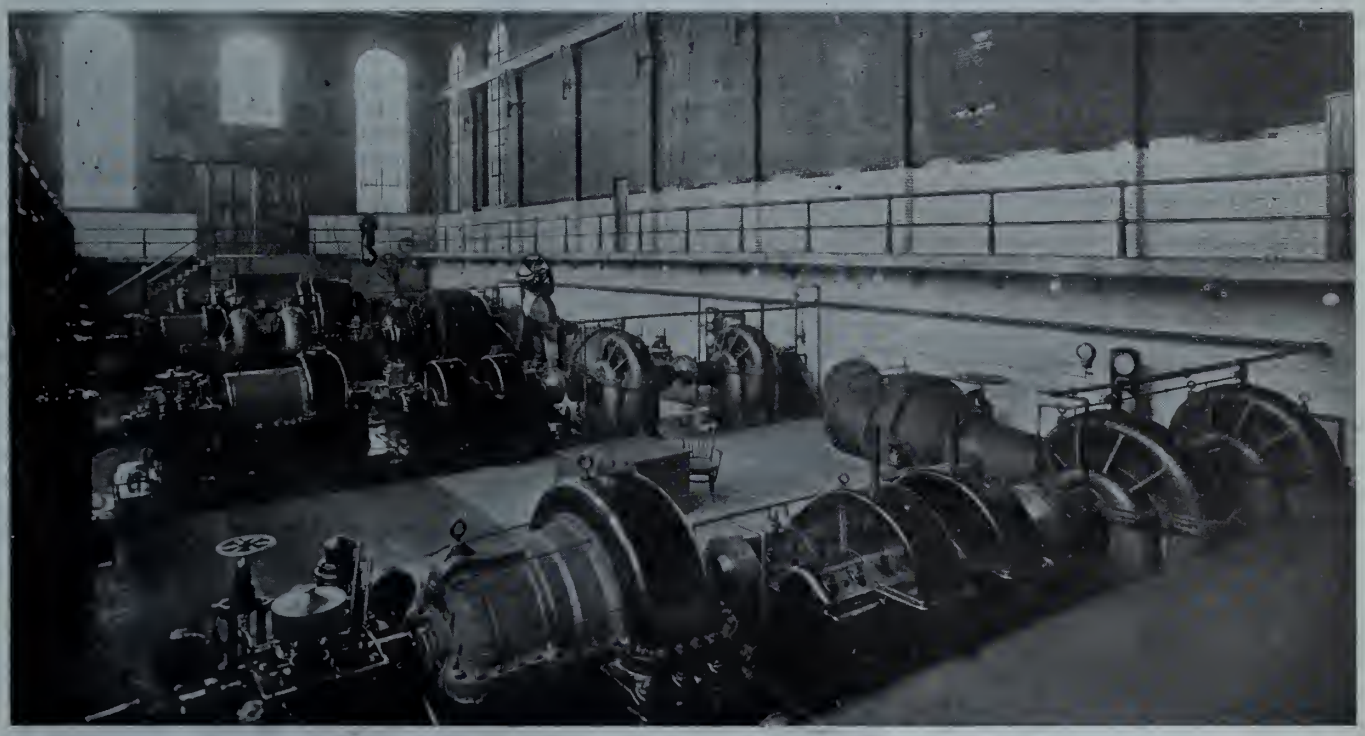
WHEN the babbitt is being run directly into bearings, the shell should be heated to about 100 degrees to prevent blowholes. A Brinnell hardness of 23.5 for lead base and 30 for tin base alloys is considered best.

Duty Trials on Two 24-Million Gallon Pumping Units

Contributed

The pumping engines whose performances are recorded in the following report are driven by De Laval steam turbines, and form part of the installation at the Main Pumping Station, Toronto Waterworks. The duty trials were made March 6 and 8, 1917, by Robert W. Angus, professor of Mechanical Engineering, University of Toronto.

ALL of the water used by the City of Toronto is pumped through the Main Pumping Station at the foot of John Street. This station is equipped with a number of steam driven pumps and also a number of electrically driven units, the latter receiving electric current from the general city supply. In so far as the electrically driven units can be operated without raising the city's power peak, they are kept in service, but whenever the electrical operator finds that the peak is being approached, he has one or more electrical pumps stopped and then the delivery pressure of the station may slightly decrease while a steam pump is being brought into service, but, on the whole, these variations in pressure and in supply are not noticeable in the city.



GENERAL VIEW OF PUMPING WITH UNITS UNDER TEST IN FOREGROUND.

Description of the Units

Some few years ago it was decided to increase the pumping capacity of the Main Station, and, with this in view, a new pump room with adjacent boiler room was built. The pump room now contains five pumping units, two of which are driven by induction motors, and three of which have been built by the De Laval Company, and are driven by steam turbines. It is with two of the latter pumps that the report deals.

Each unit consists of a De Laval steam turbine connected through a reduction gear to a pair of centrifugal pumps, which are connected so as to work in series.

The units are exact duplicates.

The turbines are of standard De Laval construction, type 1,600 T. D., for steam pressure of 150 pounds, and a vacuum of 29 inches, the normal speed being 3,430 revolutions per minute. Each is direct-coupled to a speed reduction gear having a ratio of 33 to 197, so that the pump shaft rotates at normal speed of 575 revolutions per minute.

The steam supply pipe is 4½ inches, with 36-inch exhaust to a standard Wheeler surface condenser, so placed that all the water delivered by the unit passes through it as cooling water before reaching the main pumps.

The vacuum pump is a 20-inch x 40-inch Rotrex pump built by the C. H. Wheeler Company, and is direct connected to a 7-inch x 7-inch engine designed for a normal speed of 200 revolutions per minute, but which ran at a much lower speed during the trials. The exhaust from this engine is delivered back into the steam turbine somewhere near the middle stage, and is made use of in doing work there.

The boiler feed pump is chain driven from the pump shaft. It is a Goulds single acting triplex plunger pump with plungers 3½-inch diameter and 6-inch stroke, and in one of the units the crank shaft driving the plungers turns at about 47 revolutions per minute, a speed which is too low to supply the necessary feed to the boiler for this pumping unit; in the other unit the speed is 66 revolutions per minute, which is satisfactory.

There are two single stage double suction pumps on each unit, the two pumps being piped together in series. There are no outside guide vanes, but the castings are of the volute form and the pumps run very quietly. The name plate states that the pump is of Type P-24, and is designed for a total head of 250 feet, and a discharge of 20,000 U.S. gallons per minute (which is equivalent to 24,000,000 Imp. gallons per 24 hours) at a speed of 575 revolutions per minute.

The water piping begins with a 42-inch suction, which is the size of the inlet to the condenser. At the condenser outlet the diameter is reduced to 36 inches and this is again reduced to 24 inches where it enters the pump. The series piping between the pumps is 30 inches, being reduced to 24 inches at the point of connection with each pump. To the discharge end of the pump a 24-inch x 36-inch tapering enlarger has been

attached to connect with the 36-inch discharge main. The inlet and outlet openings on all the pumps are 24-inch diameter.

The pump impellers are of bronze.

The Duty Trials

The duty trials on the machines were run on March 6th and 8th, 1917, respectively, and in order to see that the conditions were uniform before the tests began, the machines were run for at least an hour under full load immediately preceding the duty trial.

The boiler fires were properly cleaned, and everything put in as good condition as possible to insure uniformity, but some slight variations naturally occurred. It was necessary to run the trials during the daytime, owing to the demand for water in the city, and therefore an effort was made to start as near seven o'clock in the morning as possible, although in both cases the trials did not begin till nearly an hour later.

The city's electrical power peak occurred shortly after the trial began in each case, and the electrical pumps were therefore shut down, causing a heavy draught on the pump under test. There was a consequent decrease in pressure, but as the discharge increased at the same time, the load on the steam turbine driving the pump did not vary greatly. Throttling of the pump discharge was temporarily resorted to, in order to prevent undue fluctuations, and another steam pumping unit elsewhere in the station was put into service as quickly as possible, but the extra draught of steam from the boilers caused some slight variations in steam pressure.

All of these variations, however, were of short duration and were productive of but slight inconstancy in the general conditions, and the machines were given exceptionally steady loads during their entire trials.

Conditions Governing the Trials

In the contract dated August 14th, 1914, the conditions governing the conduct of the duty trials are given, and the following clauses referring thereto are copied here for reference:

"54. Each turbine shall have sufficient power capacity when connected by flexible or other approved coupling to the centrifugal pump to raise from the suction conduit directly into the pipe system of the city not less than 24 million Imperial gallons of water in 24 hours, against a pressure difference of 107 pounds per square inch between suction and discharge mains, the pressures to be measured at approximately the same level.

"57. The turbine to be designed for speed not in excess of 4,000 revolutions per minute, and the centrifugal pump to to be operated at speed not exceeding 600 revolutions per minute, with provision for a ten per cent. (10%) increase in speed, if necessary.

"58. The pumping capacity of the unit shall be determined by Venturi meter measurement, and if the capacity of the unit, when running the pump at a speed not in excess of 600 revolutions per minute, and a turbine speed not exceeding 4,000 revolutions per minute, is less than 24 million Imperial gallons, the Commissioner may deduct from the amount to be paid to the contractor two and one-half per cent. (2½%) of the contract price for each one per cent. (1%) less than the specified capacity, at the specified pressure, and pro rata for fractional parts.

"If the capacity as shown by the official trial of the unit does not reach 92% of the specified capacity, the Commissioner may, at his option, reject the unit, and in case of such rejections the contractor shall return all moneys paid him on account, and shall, without compensation, allow the unit to remain in the service of the city and under the control of the commissioner for such reasonable time as may be required to install a new unit.

"The steam turbine driven unit shall perform a duty of not less than one hundred and twenty million (120,000,000) foot pounds for each one thousand (1,000) pounds of steam containing less than 1½% of entrained water, as determined by throttling calorimeter measurements, used by the engine and any auxiliary pumps supplied by the contractor and operated during the duty trial, when pumping not less than 24 million (24,000,000) Imperial gallons in 24 hours.

"In computing the duty, the work performed by the unit shall be based upon Venturi meter measurement. The head for computing the duty shall be that shown by an accurate pressure gauge attached to the discharge main at a point inside the engine room and beyond the last pump, less the reading shown by a gauge attached to the supply conduit at or near entrance to pumps, an allowance being made for any difference in the level of the gauges. No allowance shall be made for friction of water between the gauge points, between which shall be situated the complete machine as supplied by the contractor.

"In computing the duty, the total steam used, including that used by jackets, air pumps, air compressor, boiler feed pump and any other auxiliary pumps, shall be charged up to the engine. No allowance shall be made for any heat returned to the boilers derived from the exhaust steam from the turbine or from any auxiliary.

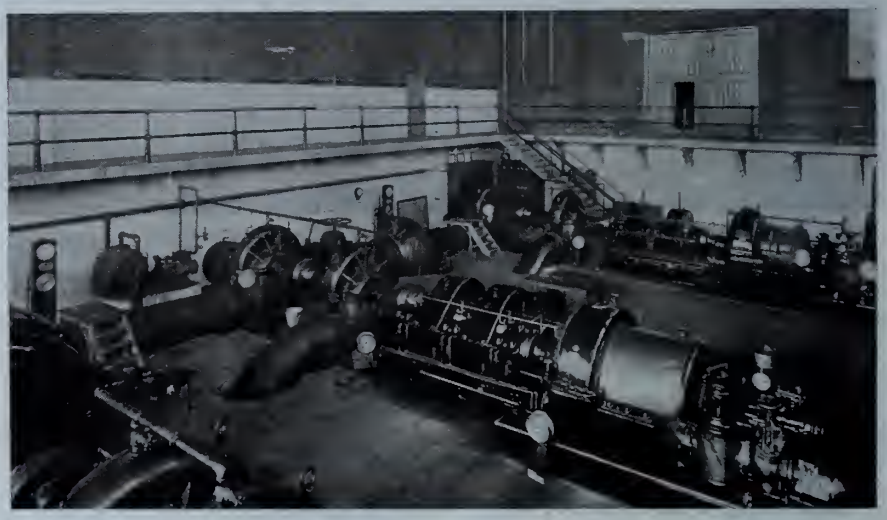
"After the unit has been in successful operation for sixty (60) days, a duty trial of 24 hours' duration shall be made. The unit shall be operated continuously at its rated capacity, against a pressure difference of 107 pounds per square inch as above specified, and shall be supplied with steam of not more than 150 pounds per square inch, by gauge, at the boiler, and containing not more than 1½% of entrained moisture.

"During the trial the unit shall be operated by the regular engineers of the station, at the speed and pressures specified, but otherwise shall be under the control of the contractor. The trial shall be conducted by the Commissioner, or persons appointed by him, in the presence of a representative of the contractor. The city shall pay all expenses of the trial, except that the contractor shall pay his own men.

"If the duty shown by the official trial of the steam turbine driven unit shall be less than 120,000,000 foot pounds, the Commissioner shall deduct from the amount to be paid the contractor the sum of $2,500 for each 1,000,000 foot pounds unperformed below 120,000,000 foot pounds, and pro rata for fractional parts down to 115,000,000 foot pounds.

"If the duty shown by the official trial of the steam turbine driven unit shall be less than 115,000,000 foot pounds, the Commissioner may, at his option, reject the unit; and in case of such rejection, the contractor shall return all moneys paid to him on account, and shall, without compensation, allow the unit to remain in the service and under the control of the Commissioner for such reasonable time as may be required to install a new unit.

"If the duty as shown by the official trial of the engine exceeds 120,000,000



VIEW OF UNITS UNDER TEST FROM OPPOSITE DIRECTION.

foot pounds, the city shall pay to the contractor the sum of $1,500 for each 1,000,000 foot pounds above the stipulated duty, and pro rata for fractional parts, but the bonus shall not exceed $7,500.

"59. While the duty specified for the steam turbine driven unit is 120 million foot pounds, tenderers are requested to state any higher duty they are prepared to guarantee, and any higher duty guaranteed, together with the contractor's ability to fulfil same, in the opinion of the Commissioner, will form a factor in the awarding of the contract. Should the contractors guarantee a duty in excess of that specified, when using saturated steam containing not more than 1½% of entrained moisture, the duty guaranteed will be substituted for this amount, and for each one million (1,000,000) foot pounds in excess of the guarantee the corporation shall pay to the contractor the sum of fifteen hundred dollars ($1,500), and pro rata for fractional parts, but the total bonus shall not exceed seven thousand five hundred dollars ($7,500). Should the duty as shown by the official trials be less than the guarantee the Commissioner shall deduct from the amount paid to the contractor the sum of two thousand five hundred dollars ($2,500) for each one million (1,000,000) foot pounds unperformed, and pro rata for fractional parts down to five million foot pounds less than the guaranteed duty.

"If the duty as shown by the official test be more than five million foot pounds below the guaranteed duty, the Commissioner may, at his option, reject the unit, and in case of such rejection, the contractor shall return all moneys paid to him on account and shall, without compensation, allow the unit to remain in the service and under control of the Commissioner for such a time as may be required to install a new unit, and shall fully reimburse the city for any loss or damage suffered by reason of the contractor having failed to fulfil his guarantee."

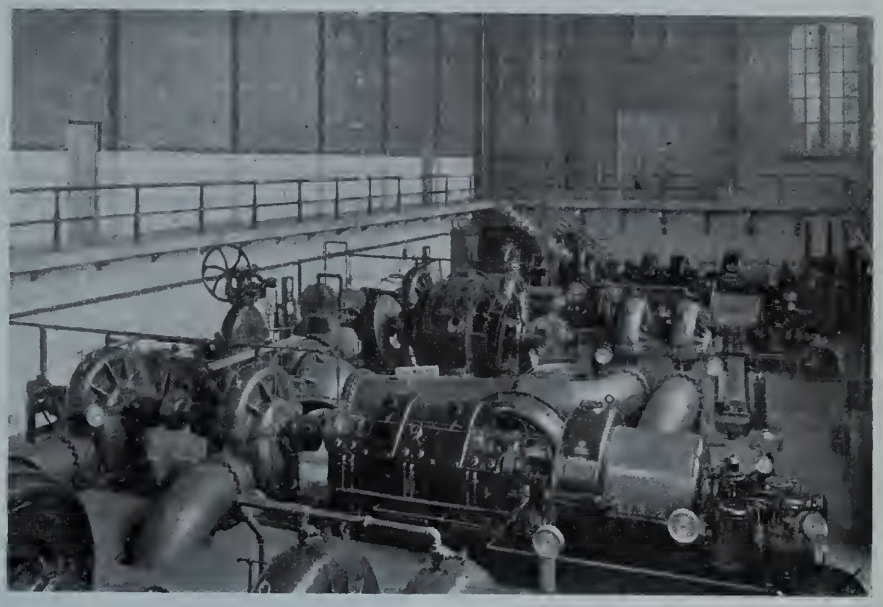
In accordance with clause 59, the contractors guaranteed a duty of 141.5 million foot pounds of work per 1,000 pounds of stream used, and this duty was therefore inserted in the contract.

Details of the Trials

The duty trials were run in exact conformity with the specifications, with the single exception of the duration of each, which is specified as twenty-four hours. On discussing the matter with the city's engineers, it was found that the conditions in the station made such a long run very undesirable, and it was agreed that the run should be shortened to ten hours. The contractor agreed to this, and a copy of his letter relating to the matter accompanies this report.

There is no doubt that the results for the ten-hour period would be practically identical with those for twenty-four hours.

The specifications require that the gauge pressure on the boilers supplying the turbines shall be 150 pounds per square inch. A battery of four boilers was used in each case, and on top of each boiler there is a stop valve bolted to the steam drum, and from the top of this stop valve the steam pipe from the boiler leads to a header which is common to all boilers. To this header the supply pipe for each pumping engine is connected by a fairly long, well-lagged pipe.



GENERAL VIEW OF STATION. NOTE ELECTRICALLY-DRIVEN PUMP.

To avoid any possible sources of loss in the boiler stop valve, the gauge used on the trial was connected to the steam pipe within six inches of the stop valve. The gauge pipe was so arranged that the gauge was brought down to the level of the fireman's eye, and correction was made for water column. An observer remained constantly in the boiler room so as to keep this pressure uniform, and readings were noted every 15 minutes.

The quality of the steam was taken by throttling calorimeter attached to the steam pipe about six inches from where it entered the turbine stop valve. For the purpose of determining the quality, the engine pressure was taken and is also recorded; it was taken at the point where the calorimeter was attached. These readings were at 15-minute intervals.

Exhaust Pressure and Temperature

To determine the exhaust steam condition, both a mercury column and a thermometer were used, the mercury column being attached to the turbine casing slightly below the level of the main shaft, while the thermometer was inserted in a cup in the exhaust pipe about half way between the turbine casing and condenser. Much care was taken to push the thermometer well into the cup, so that the bulb was at least 9 inches in from the pipe wall, and the mercury column connections were also carefully tested for leakage. A comparison of the two readings given in the table herewith shows that the temperature is lower than that corresponding to the mercury column, possibly due to the difference in location, and partly to the presence of air in the exhaust. Both results are quite accurate and equally reliable.

Speeds

The speeds were taken with an ordinary revolution counter, or else were actually counted, those on the main pump being at 15-minute intervals; the others were not so frequent. It was not possible to get the speed of the steam turbine directly, and hence it had to be calculated from the pump speed, using the gear ratio given by the contractor of 197 teeth in the gear to 33 teeth in the pinion. The pump and turbine speeds were well below the maximum specified.

Steam Used During Trial

To get the steam used during the trial, the ordinary pipe for delivering the condensate into the feed tank was broken and a connection put in so that the water was delivered into a storage tank, from which it was run into a tank on scales as desired. The leakage from the air pump glands was caught and has been added to that coming directly from the air pump discharge. There was only one trap on the turbine plant, and, as it was plugged, no leakage occurred there.

On the first unit tested the gland leakage was not great, but as it was in the form of steam it could not be measured. In the second unit the leakage was much more marked, due to defective carbon rings, but the steam thus escaping would not have formed any appreciable proportion of the total, and its effect on the duty would be very slight.

The weighing tank was capable of holding a net weight of only about 1,000 pounds, and, in order to keep well within the limits, the weight of steam condensed every three minutes was taken. In order to have no error due to the storage tank, the water in it was brought to the same level at the end of the test

as at the beginning. All weights were taken to half pounds.

The steam used by the air pump is automatically included with that from the turbine, and the feed pump was chain driven from the pump shaft.

Water Pressures

For convenience and greater accuracy the pressure and suction gauges were both piped to the same point, close to the suction inlet pipe, and in the results allowance was made for the difference in levels between them.

Before the test began, considerable discussion took place between the contractors and myself regarding the position of the discharge gauge connection, and also as to whether velocity head was to be allowed for. In this connection it is pointed out that the suction pipe up to the condenser is 42-inch, and the discharge outlet from the pump 24-inch, and a tapering enlarger and valves are used to connect the 24-inch pump outlet to the 36-inch delivery pipe provided by the city. The difference in pressure between the two ends of this enlarger was slightly over 7/10 pound per square inch, being greater at the 36-inch end, and amounted to about 7/10 of one per cent. of the total head.

The nature of the specifications prevented allowance being made for difference in velocity head between suction and discharge pipes, and it was also agreed that the discharge connection should be placed on the outlet from the pump where its diameter was 24-inch, and the results are reported on this basis.

The discharge pressures were taken with a sensitive Bourdon gauge, and the suction pressures by mercury manometer; there was always a slight pressure in the suction pipe at its centre line.

Both readings were taken every five minutes, the discharge gauge being carefully calibrated.

Measurement of the Water Pumped

The specifications required that the water pumped should be measured by Venturi meter, and both of the pumps discharged through a 36-inch meter with 21-inch throat. The quantity was calculated from readings of a mercury manometer, using the coefficient supplied by the Builders Iron Foundry, the makers of the meter, who state that a manometer reading of 5.07 inches of mercury corresponds to a discharge of 25.30 millions of Imperial gallons daily.

Readings were taken on the manometer at five-minute intervals, and in order to check the recorder for the meter, readings were also taken on it, and the results are included for reference.

Observers and Representatives

The observers were all fourth year students in engineering at the University of Toronto, and were well skilled in the work required.

The contractors for the units were the Turbine Equipment Company, Toronto, who were represented by their manager, Mr. Austin, and also by Messrs. Salt and Petersen of the De Laval Turbine Company, Trenton, who designed the machinery and built much of it. The writer represented the city of Toronto, and personally conducted both the trials, and desires to express his thanks for the co-operation of the above parties, and also of Mr. James Milne, Mechanical and Electrical Engineer of the Works Department.

Remarks on the Trials

The results obtained on the units are a matter of great satisfaction, partly because they have so far exceeded the guarantees of duty, and partly because the results are exceptionally high for this class of pumping unit, and have probably not ever been exceeded by any similar unit running under similar conditions of steam and of equal water pressures. The city is to be congratulated on having pumps which will give such good results.

Respectfully submitted,
ROBERT W. ANGUS.

ROBERT W. ANGUS.

Toronto, March 20th, 1917.

ADVANTAGES OF OIL FUEL LOCOMOTIVES

By O. C.

IN the case of a locomotive burning oil fuel, the fire can be instantaneously adjusted to suit the load, which varies almost from minute to minute with the speed and gradient. So perfect is the control that the steam pressure can be maintained inside a total variation of five pounds with changes in load of 50 per cent. and over. An important feature is the rapidity with which a head of steam can be obtained; an engine can be moved under her own steam within 35 minutes of the full oil-burners being lighted. The practice on railways using oil is to have a stationary boiler always in steam at each round house, from which connection is made to the dead engine through a three-way cock in the steam pipe leading from the steam stand on top of the fire-box to the burner. By this means the burner can be started from cold until there is sufficient steam generated in the engine itself to keep the burner going.

The advantages of the use of oil are specially noticeable in the round house or shed when squaring up after a day's work. There are no fires to be raked out; no flues or soot boxes to be cleaned; no coal to be stacked, weighed or otherwise handled. A saving in cost of equipment is represented in the absence of fire-rakers, flue brushes and shovels all of which are unnecessary on an oil-burning locomotive. Further, when engines are engaged in switching and shunting operations, they frequently have to stand idle under steam for hours at a time. The burners in such cases can be cut down to the minimum, or even extinguished, as an engine will always retain sufficient steam to start up the burners again when required.

Modern Steam Power Plant and Its Appliances--I.

By John H. Hale*

Despite the wonderful developments of hydro-electric power generation, the modern steam power plant occupies a firmly established position in engineering effort from which its removal, if it take place at all, will never be more than temporary. The economies possible in large plants and the duty of all engineers to adapt such methods to their small individual plants wherever possible is emphasized by the writer.

THIS subject is of indirect and personal interest to the owner and engineer of every power plant. The intention is, if possible, to awaken to a conscious realization what is in a majority of cases an utterly careless and indifferent attitude to the engine and boiler rooms under their care. To some, it may seem that there is not much involved, and that other and more pressing questions come forward for adjustment first. I want to ask you,—"Are your engine and boiler rooms all they should be: All they might be?" And do each of you realize that they are at present what you have made them?

Initial Errors

A great many mistakes are made in laying out and building a steam plant, not only from inexperience, but also from trying to reduce the first cost of installation. As you are all aware, any apparatus or safety appliance can be installed far more cheaply before the plant is in operation than afterwards; and the safety appliances should be considered not only in large plants, but also in any small plants. The question arises—"Is it necessary when you are building a plant for yourself to have these safety appliances or mechanical devices?" This question must be considered very carefully by the engineers in charge, also the owner of the plant. First of all, every plant cannot have the same mechanical devices, as nearly every plant is run under different conditions and for different purposes.

Another mistake made when installing a plant is that of trying to do the work too quickly. The company that is waiting to have the plant in operation is impatient and sometimes you have not the material on hand that you should have, and many times you have to make a temporary job, to get the plant started at a few hours' notice, and cannot get the chance later to change the work that was not done properly in the first place. Operating a plant under the above mentioned conditions may be a great loss and disadvantage to you, financially and practically. Then if you want to make any change, it means a shutting down of your plant for a certain amount of time, sometimes much longer than you expected. There you have another loss, which sometimes runs to a large amount.

In very many cases, certain mechanical devices, or appliances, in connection with a steam plant, are condemned by the engineer in charge. It is quite true that some of these mechanical devices are not answering the purposes they were intended for, but I am sorry to say that a great many power plant owners do not consider the position from the point of view of those in charge of their plants. A great many mechanical devices and other machinery are condemned by inexperienced men, as they believe anything mechanical should work mechanically without attention.

As stated before, some of these devices may not be suitable for your plant and conditions, but may be of first-class service for a different plant for which they are intended, and for this reason before condemning any of your machinery or appliances, make a careful investigation, to see if they were made for the purpose you want them. Are they large enough? Do you give them proper attention? Inquire of other plants of your type and size, and you will be in a position to correct these aforesaid troubles.

JOHN H. HALE.

Engine Room Appearances

Visiting an engine room will give you a fair indication of the engineer in charge, and with this most of you will agree. The engine room in which the distinct knocks tell of each revolution the engine or engines are making, the hiss of steam from leaky joints, the tools, oil, water and waste lying all over the floor all indicate in a fairly reliable way what the engineer is in action and appearance without seeing him.

It is not necessary that tiled floors and white enameled brick walls should be part of the equipment, but it is necessary that every engineer should see that the plant of which he has charge is kept in such manner that it does not reflect injuriously on him and his work, in the eyes of his present or prospective employer; and these latter should see to it that an engineer and his engine room do not impress unfavorably an outside estimation of themselves. This may be prevented by their insisting on cleanliness and tidiness in everything pertaining to the power plant, and their encouragement and recognition, of the engineer doing so. Boiler rooms generally suffer more than engine rooms, due largely to a poor layout, in the matter of access and light for inspection, and being thus under a cloud as it were, do not draw attention or criticism to the same extent. Not enough interest is taken in them by engineers, and, in fact, their absence from them is marked. This should not be allowed, because they have graduated from the coal shovel, and, while naturally proud of the achievement of having left it behind, they should not be lacking in care for the boiler room, as this is the most dangerous and most important part of the plant.

We will go a little farther into the economy question, which is very important. When a large manufacturing company is building a new factory, the first question, generally, is the power question—How they can buy or generate cheap power, so they may compete with other manufacturers?

It would take too much time and space, if I were to take this question in detail from the smallest to the largest power plant.

The Larger, the Cheaper

It is well known that the larger the power plant the cheaper the power may be generated. However, from 15 per cent. to 40 per cent. increase in efficiency could be derived from the majority of small plants by proper care and proper attention. There are a number of stokers on the market, and from practical experience it will be found that the highest efficiency in regard to firing is obtained from automatic stokers.

At the Grand Trunk shops power plant, we are equipped with four chain grate stokers, built by the Green Engi-

*Executive Secretary, Canadian Association of Stationary Engineers.

neering Co. of Chicago. Each grate has an area of 72 sq. ft. I personally consider this stoker one of the greatest labor savers on the market to-day, under normal conditions. Now this automatic stoker having a grate surface of 72 sq. ft. can burn say 18 lbs. of coal per sq. ft., and suppose the demand for steam increases, and you have to increase the feed of your coal, say from 18 lbs. to 20 lbs. per sq. ft., is it possible for you to get the same efficiency, not only from your coal, but also from your boilers, when you are overloading your stokers and boilers?

You have to travel the stoker at a great speed, and the result will be that a large amount of combustible will run down to the ash pits, your combustion chambers will not be large enough to effect combustion of the extra amount of coal, and the temperature of the flue gases increase, and the result is that your efficiency is escaping through the chimney. To be equipped with alarm column for low water, and high water, is a great advantage, especially for small power plants, in which, I am sorry to say, you will not find the engineer or man in charge in his boiler-room except when he comes around to put on a fire, or oil up his machine; then maybe he will have to go to repair a belt, etc., and sometimes does not go to the boiler room till the alarm whistle notifies him that the water may be too high or too low in his boiler. As I said before, this device is a great advantage, but I may say it is, or rather may be, a great disadvantage also; for if this, or any other kind of water column is not blown down at different times during the day, it may choke up with mud, with the result that the water level will remain the same, and the alarm whistle will not blow. In most of the new power plants, small or large as the boilers may be, the man in charge may depend on this alarm to warn him, but he may wait too long, and before he gets back his tubes or boiler may be damaged, or possibly blown up. It is a very good policy for a steam plant to have a recording steam pressure guage connected with the water column, as it will record every time that the man in charge blows down the water column.

Feed Pumps

A very important item of boiler equipment is the pump or other device for feeding the boilers with water. In a great many power plants you cannot find more than one pump for this purpose and this is a very great mistake. Every engineer knows that if this boiler feed pump fails the whole plant has to be shut down to prevent a boiler explosion or rather other damage, due to running too long with low water in the boilers, while trying to get the pump in operation without shutting down the plant. For this reason, not only every engineer, but also the plant owner should insist upon having a duplicate set of pumps or other devices for feeding water to the steam boilers, not only to prevent shutting down, but also for the prevention of further serious damage.

THE EFFECT OF SPELLERIZING ON THE LIFE OF STEEL TUBE

THE beneficial results on the longevity of steel tube manufactured by the spellerizing process are pointed out in an article in the "Compressed Air Magazine," the process having been devised to overcome the tendency of corrosion in the smaller sizes of steel piping in which the greatest corrosion in service occurs on account of the thinness of the metal. Large sizes, being made from heavier plates of more uniform quality are not so seriously affected by corrosion.

The process consists in subjecting the metal bloom to the action of rolls having regularly shaped projections on their working surfaces, then subjecting the bloom while still hot to the action of smooth faced rolls and repeating the operation, the surface of the metal thus being worked so as to produce a uniformly dense texture better adapted to resist corrosion, especially in the most objectionable form of pitting. The process is quite analogous to the kneading of dough and operates upon the metal all through instead of merely on the surface. The aim is to make the metal uniform and without the spots of varying texture from which pitting results.

Uniform Results

As the process is entirely mechanical and does not in any way depend upon the skill of a workman, uniform treatment and results are assured. The process is applicable to the smaller sizes of pipe, say up to 4 inch.

Pipe has been made by this process for ten years in increasing amounts. The official records of the American Iron and Steel Institute show that during this period the percentage used of steel pipes has increased from 74.3 to 87.9 per cent.

Appended are some special experiences as to the use of this process and its effect upon steel pipe in actual service.

H. J. Macintire, Professor of Mechanical Engineering, Washington University, says in Power:

"In the case of ordinary steel pipe, mill scale is always present, and this likewise is electro-negative to the iron. If this scale is evenly distributed, as in Spellerized steel, the self-corrosion on its account will be slight; but if it is segregated, then local electrolysis and pitting of the material will result."

Morgan M. Smith, in the October, 1913, issue of *Ice*, states with reference to the merits of the Spellerizing process:

"Steel pipe, which has been treated in such a manner as to eliminate or at least distribute evenly the mill scale may be joined with wrought iron or cast iron safely as a rule. The same stock without the treatment for mill scale will show a decided tendency to corrode when joined with wrought iron or cast iron. The so-called Spellerized steel fulfills this condition with respect to the scale."

R. B. Duncan, associated with the United Gas Improvement Company of Philadelphia, Pa., in a paper "Installation and Maintenance of Service," read before the Ninth Annual Meeting of the American Gas Institute, 1914, states:

"The steel industry has been developing a new process which, after several years' time, has given many encouraging results. By this process the steel is treated mechanically and does not in any way depend upon skilled labor, beyond keeping up the machinery involved, hence uniform treatment is assured.

"This new process is a method of treating metal which consists in subjecting the heated bloom to the action of rolls having regularly shaped projections on their working surfaces, then subjecting the bloom, while still hot to the action of smooth faced rolls and repeating the action whereby the surface of the metal is worked so as to produce a uniform dense texture better adapted to resist corrosion, especially in the form of pitting."

The Gas Record, (issue of September 23, 1914, page 222) in commenting on Mr. Duncan's paper in regard to the Spellerizing process, says:

"The consensus of opinion is that modern steel pipe, particularly if Spellerized, is as durable as wrought iron, and is, besides, cheaper, stronger and more ductile and more uniform in composition."

Pipe steel made in 1906 by this roll-knobbling process tested against pipe steel made in 1897 resulted not onl yin a somewhat greater loss of weight by corrosion of the latter, but a decidedly deeper pitting of the 1897 steel in six months than occurred in the 1906 steel in thirteen months. In comparison with wrought iron it was found that the two materials lost practically the same weight by corrosion yet the steel had the advantage of uniform corrosion since the "wrought iron skelp pitted in seven months much deeper than the steel did in thirteen months." (Prof. H. M. Howe, Am. So. for Testing Materials, 1908).

A. Sang, in a thorough resume of the question, entitled "The Corrosion of Iron and Steel" (McGraw Hill Book Co., New York, 1910), says:

"The carefully acquired experience of the largest manufacturers of tubes in the world, which induced them recently to abandon the manufacture of wrought iron pipe, teaches that the use of steel in place of iron, at least in the United States, for the special purpose of tubing is to be preferred; the tendency of steel to pit is somewhat less than that of iron and it welds at the joint fully as well."

"There is very little, if any, difference between the corrosion on the wrought iron and the corrosion on the steel pipe. If anything, the wrought iron is pitted a little deeper, i.e., the pitting on the steel pipe is probably more general all over the surface, but the pitting on the wrought iron pipe is deeper in spots that are affected." (Proc. American Gas Institute, Vol. III, 1908, page 274).

Electricity and Hydraulics

WORLD'S MOST POWERFUL LOCOMOTIVE

IN the vicinity of Philadelphia the Pennsylvania Railroad Co. has been testing the world's most powerful locomotive. This locomotive is capable of exerting a maximum horsepower of 7,000, and is intended for the mountain grade electrification between Johnstown and Altoona, Pa., around the famous horseshoe curve. During a recent test this locomotive hauled a train of 68 cars, and the regular large Mikado type of road locomotive. The steam locomotive, however, remained idle.

The mechanical parts of this electric engine were built by the Pennsylvania Railroad Company at their Juniata Shops at Altoona, Pa., and the electrical equipment supplied by the East Pittsburgh works of the Westinghouse Electric & Mfg. Company.

THE MOST POWERFUL ELECTRIC LOCOMOTIVE IN THE WORLD.

To equal the power of this locomotive it would take 100 trolley cars, or 14,000 horses, or 56,000 of the strongest men. Enough electric current is consumed bl it to light over 200,000 25-watt electric lamps; and many a town of 25,000 people has an electric light plant of smaller capacity. This is possible because of the high voltage alternating current used in distributing the strong electric power.

Exerting its maximum pulling force this locomotive will develop 7,000 horsepower, which is greater than its closest electrical rival can do. This locomotive, which weighs 250 tons and is slightly over 76 feet in length, is the first of a type that will be used on the Altoona Grade Electrilcation of the Pennsylvania Railroad, between Johnstown and Altoona, around the famous Horse Shoe curve. Two of these locomotives are able to haul a 6,000-ton train up this mountain grade at a speed of slightly over 20 miles per hour, thus relieving, when necessary, the congestion that seems apparent in that freight traffic over this division now, which is unusually heavy, amounting to as much as 300,000 tons per day. In addition to the heavy grade over the Alleghany Mountains a long tunnel, which helps to form the "narrow neck in the bottle" in operating over this division, must be passed through.

By electrification the expense of grade reduction has been eliminated and the capacity of the division will be more than doubled.

The Westinghouse Electric equipment is so designed and built that these locomotives can haul the heavy trains up hill and coast down hill at the same speed of 20 miles per hour. By the motors becoming dynamos or generator in the latter case effective braking action results without the use of air brakes, which prevents runaways. This coasting speed can be regulated just as speed up-hill or under power. Air brakes are therefore not needed while coasting, and are simply held for emergency use and for bringing the train to a full stop.

ELECTRIC POWER GENERATED BY EARTH'S HEAT

A REPORT comes from Italy of a new and unique application of Nature's resources to produce power in commercial quantities. It consists of the utilization of the steam, whch at various localities where hot springs abound is seen issuing from cracks and fissures in the earth's surface.

As far as known, no effort was ever made to exploit this source of energy previous to developments which were begun in Italy a few years preceding the war. The heavy demand for power which the manufacture of munitions created in that country and the apparent necessity for conserving fuel led to the more extensive developments of the scheme.

According to an article in "The World's Work," the reservoirs are tapped at their source by boring through from 300 to 500 feet of hard rock and conducting the steam to the surface in iron pipes. The temperature of the steam issuing from these bores varies from 150° to 190° C. at a pressure of between 2 and 5 atmospheres. Owing to the corrosive action of the acid salts in its composition, it is impossible to use the natural steam in a prime mover, but by passing the steam through the aluminum tubes of a vertical, multitubular boiler ordinary water steam is produced at 2 atmospheres pressure. The steam thus generated in the boilers is conducted, on its way to the turbines, through aluminum pipes, heated outside by a current of natural steam at 180° C. and becomes superheated to 150° C. Aluminum is unaffected by the acidic action of the natural steam.

The turbines are low pressure, exhausting to surface condensers, the circulating water being cooled by a cooling tower. The condensed steam is returned to the boilers.

It is estimated that if the various volcanic heat-producing areas of the world were thus developed, many thousands of horse-power could be generated.

At the present time the installation at Voltera is capable of generating 15,000 horse-power of electrical energy, which is transmitted to Florence and a number of other cities and towns.

SULPHUR FROM GAS ENGINES AND ELECTRICAL EQUIPMENT

By T. J.

IN the search for the economic generation and use of power, the association of gas engines as prime movers with electrical apparatus is becoming more

and more general. There is certainly much to be said in favor of this, and therefore it is all the more necessary to face such difficulties as crop up in actual practice, as frank recognition of drawbacks usually lead to the discovery of means to overcome them. Now, one of the points that calls urgently for consideration is the fact that power houses which are equipped with large gas engines, especially those working with furnace, coke oven or producer gases, present troubles in connection with the maintenance of the switch gear and electrical plant. Something is constantly getting out of order, necessitating renewals, perhaps at awkward moments, and proving in the aggregate fairly expensive. These troubles it will be found, are due to the sulphur in the atmosphere, which attacks the switch contracts, and also affects the insulation of the windings of the machines.

So far it has been found practically impossible to prevent the sulphur laden atmosphere getting to the windings of alternators, but, of course, the switch gear and transformers, etc., may be placed some distance away from the engines, and further protected by being immersed in oil. These simple precautions usually prove effective. But the question of protecting the insulation of windings has still to be solved. This is one of a number of small points of which account has to be taken when installing gas engines, but which advocates of gas engines for any and every purpose generally omit to mention.

This is the wrong spirit in which to approach such problems, in this instance, proving harmful to the advance or the use of both class of apparatus. What is required is further experimentation, both with standard materials and with substitutes therefor.

Experience has of late taught that it is a mistake to assume that any one substance is the inevitable and the only one suitable for any special purpose. Actual practice has for years been handicapped by accepting certain existing conditions as those which must limit the work in hand. Other methods and substitute materials, which have long been held taboo, have been used under the stress of circumstances and discovered to work very well. It is, therefore, unwise to assume that the producer gas is hopelessly inimical to the working of electrical plant in close proximity.

MOTIVE POWER IN NORWAY

By L. E.

THE industries of Norway have been very seriously affected by the coal shortage and the restricted imports from Great Britain, and have been compelled to solve the most difficult of many problems with which they have been faced by utilizing the natural resources of the country. Considerable attention has therefore been concentrated on the development of plants for the generation of electricity by waterpower. The future of Norway as an industrial country will depend, next in importance to the cheapness and abundance of the water power and shipping facilities, on the supply of raw materials, or to what extent the electric power used by the industries will make Norway independent of importing raw materials necessary for the industrial life of the country. Norway has no coal deposits, and is therefore absolutely dependent on the import of this raw material for its industries. As a producer of heat units coal has hitherto provided all industries, and it is here where the electric furnace as a producer of motive power will take the place of coal.

Use of Electricity

One of the most important experiments which has been under discussion and has been tried on a large scale is the replacement of the old blast furnaces, with their large consumption of coal, by the electric furnace in the manufacture of pig iron. Two-thirds of the coal consumed in the manufacture of pig-iron is used for obtaining the necessary temperature for the reaction, whilst one-third of the coal is consumed purely as a chemical agent for the reduction of the iron-oxides. By the use of electricity it would therefore appear that two-thirds of the coal consumption should be saved. Although the use of electric furnaces for the manufacture of pig iron has been fairly successful in Sweden, the attempt in this direction in Norway was a failure.

As to the cause of the failure there exists a great difference of opinion amongst experts, some giving the lean iron ore as the cause, some the construction of the furnace and the electric arrangements in connection with the same, whilst others are of the opinion that for electric pig-iron manufacture it will be necessary to use the high-grade, comparatively scarce, and expensive charcoal instead of coke, which last one will, so far as Norway is concerned, have to be the necessary kind of coal. By the use of the electric furnace in the manufacture of pig-iron and steel, there will, however, always be need for the use of coal, as the electrical heat replaces only the coal used for obtaining the heat, whilst still one-third of the coal consumed in the blast furnace will be consumed in the electric furnace doing the chemical work.

Coal Not Displaced

Although the use of electricity will play a great part in this manufacture, the consumption of coal will not entirely be replaced by electricity, and Norway will in this line of industry be dependent upon import of one of the raw materials. The consumption of coal, as now practiced in the copper blast furnaces, can be wholly replaced by the electric current. Norway has abundant deposits of copper pyrites, the mining of which is Norway's most important mining industry. The use of coal in smelting the copper pyrites is solely for the purpose of furnishing heat, and the electric smelting of copper ores is nothing more than the substitution of electric heat for the heat derived from the combustion of coal.

TRANSMISSION LINE PROTECTION

A SPECIFIC illustration of some protective measures which are deemed necessary to guard against lightning on transmission lines in high altitudes is represented by the constructional features of an electrical transmission line across the Andes Mountains in Peru, as described in the "General Electric Review."

The line in uestion, which transmits 3 phase electrical energy at 20,000 volts over a mountain summit of 16,000 ft. elevation, is run on iron poles spaced 150 ft apart. It is found necessary to use 50,000 volt porcelain insulators owing to the fact that lightning disturbances occur almost every day in the year.

The telephone line is run on a separate pole line about 250 ft. from the power line and has a grounded return.

The lightning arresters at the power station entries are of the horn gap type, connected from line to ground through a resistance. A second set of horn gap arresters are connected between phases to take care of surges on the line.

ELECTRICAL NOTES

Induction Motor.—It is proposed to instal a 3-phase, 220-volt, 60-cycle, 730 r.p.m. induction motor, belted to an overhead line shaft. The shaft is 3 in. diameter and 90 ft. long, and runs at 200 r.p.m. It carries 16 pulleys belted to a total load of about 30 h.p. The belts before starting are put to loose pulleys, so that the load on the motor at starting will be simply the friction load of the shafting. It is desired to know what size and type of motor should be purchased.

In deciding on the type of motor, it will first be necessary to know what percentage of full load torque is required at starting. This may be obtained by fixing a lever arm to the shaft and adding weights at the end of the arm until the shaft begins to turn. Then the weight in pounds multiplied by the length of the lever in feet will give the starting torque required in foot pounds. To compensate for the friction caused by side pull of the motor belt on the driving pulley a belt could be run from the driving pulley to another loose pulley, so that the tension would be about the same as in actual service. Knowing the starting torque and the full load torque, it follows that the type of motor used must be such as to provide this multiple of full load torque for starting. The maximum possible starting torque in a squirrel cage induction motor will run, on average motors, about 1.5 full load torque. In the wound rotor type it is always possible to develop a starting torque three or four times as great as the full load torque, if the proper amount of resistance is inserted in the rotor or secondary circuit. In this particular case the starting inertia is not great, and a 30 h.p. squirrel cage motor with starting compensator will probably prove a satisfactory equipment.

Efficiency, Torque, Horsepower.—Refering to an electric motor, what is meant by (a) the efficiency; (b) the torque; (c) the horsepower?

(a) The efficiency of the motor at a given load is the ratio of the power in watts supplied to the motor or as it is more commonly expressed, the percentage ratio of the electrical output to the electrical input. Thus:—

$$\text{efficiency} = \frac{\text{watts output}}{\text{watts input}} \times 100\%.$$

(b) The ability of an electric motor to do useful work is due to a force which tends to rotate the armature as long as the electric current is supplied to the motion. The armature shaft transmits this turning effort to the pulley which drives the belt and is said to exert a torque. The pull on the belt in pounds multiplied by the radius of the pulley in feet gives the torque in foot pounds. Thus, if, at the circumference of a pulley of 1 ft. radius, the pull on the belt is 400 pounds, the torque developed is $400 \times 1 = 400$ foot pounds.

(c) The unit of work is the foot pound. If we consider the time taken to do work we bring in the question of power, for power is the rate of doing work. For practical purposes, the term horsepower is used, which unit is equal to 550 foot pounds per second or 33,000 foot pounds per minute.

In the case of the electric motor, the number of foot pounds of work done by one revolution of the pulley is equal to the pull in pounds on the belt at 1 ft. radius multiplied by 2 pi, for 2 pi is the circumference in feet of a circle of 1 ft. radius. This is equivalent to saying the work done in one revolution is equal to 2 pi T where T is the torque or pounds pull at 1 ft. radius. The foot pounds of work done in one minute will equal the number of revolutions per minute multiplied by 2 pi T, hence the horsepower will be

$$\text{H. P.} = \frac{2\,\text{pi}\,T \times \text{R.P.M.}}{33000}$$

Size of Belt.—A 35 H.P. motor runs at 550 revolutions per minute and will be used to drive a line shaft pulley by a belt. What size of belt should be used?

The torque is given by:—

$$T = \frac{\text{H. P.} \times 33000}{2\,\text{pi} \times \text{R.P.M.}} = \frac{35 \times 33000}{2 \times 3.14 \times 550} =$$

foot pounds.

The torque being 324 foot pounds, by dividing the torque by the radius in feet we obtain the pull in pounds on the belt.

The radius R is 9 in. or ¾ ft.

T = 334 foot pounds.

Pounds pull = T ÷ R = 334 ÷ ¾ = 445 pounds.

Allowing a tension of 100 pounds per inch width for a good leather belt, the width of the belt will be 445 ÷ 100 = 4.45 in .or 4½ in. approximately.

Efficiency Calculation.— (a) I would like to find the efficiency of a 500 volt, 80 H.P. shunt wound, direct current motor. The ammeter reading is 135 amperes at full load and the load is fairly constant.

(b) We have a 10 H.P. 220 volt shunt wound motor on hand. Will it be possible by inserting resistance in the circuit to operate it in 500 volts?

(a) As before stated in this column the commercial efficiency is $\frac{\text{output}}{\text{input}}$, and the output at full load is 80×746 watts since there are 746 watts to a horsepower.

The input is the voltage multiplied by the current $= 500 \times 135$ watts.

Hence the efficiency full load is:

$$\frac{80 \times 746}{500 \times 135} \times 100\% = 88.5\%.$$

(b) As you suggest, the motor may be run on 500 volts providing a separate resistance is provided in series with the armature and field circuits respectively before connecting across the 500 volt line. To find the size of each resistance you will need to know the armature current and the field current; then since the voltage drop across each resistance is 500—220 = 280 volts and is the same for both, the amount of resistance is found by applying Ohm's Law:

$$\text{Fields resistance in ohms} = \frac{280 \text{ volts}}{\text{field current}}$$

$$\text{Armature resistance in ohms} = \frac{\text{armature current}}{280 \text{ volts}}$$

This arrangement should only be used when the load on the motor is constant, otherwise the variation in torque will produce unstable conditions in the machine. Of course the power lost in the resistance does no useful work and therefore this method is very inefficient.

Cost of Operating Motor.—Please advise how to figure the cost of operating any size motor, either alternating or direct curent, when the cost of power is rated in dollars per kilowatt hour.

If the horsepower and the efficiency of the motor are known, the input is found by converting the H.P. to watts and dividing by the efficiency. Thus:—

$$\text{Electrical input} = \frac{\text{H.P. developed} \times 746}{\text{efficiency}}$$

watts.

Dividing the watts by 1,000 gives the input in kilowatts, which multiplied by the rate (dollars per K.W. hr.) will obtain the cost of operating the motor in dollars per hour.

Induction Motor Starters. — What methods are used for starting squirrel cage induction motors and wound rotor induction motors?

It is customary to start small induction motors up to 5 H.P. by connecting their terminals directly to the line. But with the larger sizes the current taken in starting is excessive and some form of starting device must be used. The device most commonly used for starting motors of the squirrel cage type is the auto transformer also called the starting compensator, which reduces the starting current by cutting down the voltage applied at the stator terminals. As soon as the motor has come up to normal speed, the compensator is cut out of the circuit, and the switch thrown to running position at which the stator or primary terminals are connected directly to the line.

The wound rotor type, with its rotor terminals brought out to slip rings, has a variable starting resistance, usually a drum controller, connected across the slip rings, which reduces the heavy currents in the rotor phases at starting. When the motor comes up to speed the resistance is cut out and the short circuiting brushes again lowered on the slip rings.

FIREPROOFING BY PAINT

By O. C.

IN a sense, all painting is fireproofing; or, more properly speaking, it is fire-retarding. There are some paints made specially for fireproofing purposes, though the number of such paints is small. Most fireproofing consists in the application of some chemical solution to the raw wood that will prevent combustion; and over this paint may be applied, or, as happens in many cases, varnish or wood finish of some sort. There are many chemicals that are useful in this connection, and some are very cheap and simple. Alum is one, lime is another.

A certain master painter uses the following formula with much success: Place some fresh lump lime in a barrel, and sprinkle water over it until it crumbles into dust. Then sift it through a fine sieve, and to every 6 qt. add 1 qt. of salt and 1 gal. of water; then place on a fire and boil, skimming it occasionally. To each 5 gal. of this liquid add 1 lb. of pulverized alum, ½ lb. of pulverized copperas, and while stirring the mixture add 12 oz. potash, also 4 lb. fine clean sand. If color is desired, any pigment may be added that will not be affected by lime; any of the earth colors will do. This paint or liquid must be applied with a fibre brush, for it would injure bristles. By adding the proper coloring the effect on a wooden roof will be quite as fine as slates. It also stops leaks in the roof, if made thicker for that purpose; prevents the growth of moss by keeping the water from saturating the wood, and—the principal object—makes it impossible for the shingles to burn. This coating is also very durable.

A different but very good fireproof paint may be made as follows: Mix together one measure of clean fine sand, two measures of sifted wood ashes and three measures of powdered lime. Mix, or better still, grind in a hand mill, with raw linseed oil, or boiled oil as preferred, the latter requiring no driers, while the former does. Apply the first coat thin, let it become hard-dry; then apply the second coat, made stouter than the first.

Steam and Its Generation

ECONOMICAL USE OF FUEL URGENT

TALKING to a representative gathering of men who are to assist the Fuel Administration in the different States, at their meeting in Washington with Dr. H. A. Garfield, Van H. Manning, director of the Bureau of Mines, Department of the Interior, said concerning the necessity of urging the economical use of fuels:

"The economical use of fuel has proved to be no simple problem. The coal, the equipment, and the human variables make hard and fast general rules impossible. The Bureau of Mines has carried on extensive experiments to determine the fundamental principles of the combustion process and of furnace design, and, at the same time has been making practical application of improved practice in government power plants. Many publications are available which show the progress of the work along these lines. Americans have been as wasteful of coal as of other resources, largely because coal has been abundant. To many consumers it has seemed hardly worth while to give time and thought to the saving of coal.

"Conditions have suddenly changed. To-day it is everybody's business to save coal. Coal is the foundation stone of industry. Without it the production of equipment for war must halt. Transportation facilities must stand still. One man's careless and wasteful use may mean an idle factory or a cold house for his neighbor. With the world looking to us largely for its coal supply, with increased demands at home, with a scarcity of available labor, with overtaxed transportation facilities, the consumer of coal must pause and give serious consideration to the problem which confronts the country.

Saving Through Intelligent Consumption

"If the consumers can be aroused to an intelligent consideration of the burning of coal, they can begin to save ten per cent. of the production, (600,000,000) at once. With more effort, through instruction and a moderate remodeling of coal burning equipment, which could all be accomplished during the war, a further considerable saving can be made. The possible coal saving when present practice is compared with the best ideal practice is very large. If it were possible to supply the need of this country for light, heat, and power, through the highest type of mechanical devices, and if we could make a skilled coal user out of the average user, we could probably get along with half as much coal as we are now consuming. This ideal is far beyond present realization.

"The immediate problem is a difficult one. We cannot scrap all out of-date power plants. We must start by doing the best with what we have. We must begin saving coal at once. The problem is personal. It deals with the human element. We must reach the man with the shovel.

Household Consumption

"About fifteen million people shovel the twenty per cent. of our coal used for domestic purposes. Only about two hundred and fifty thousand firemen shovel the sixty-odd per cent. of our coal used by power plants and railroads. While we must appeal to the householder to serve coal it is vastly more important to reach the fireman through whose hands the larger part of our coal passes.

"The householder must realize that when he throws a shovelful of anthracite coal into his furnace its value is equivalent to half a pound of sugar, or half a loaf of bread, or a pint of milk. He must appreciate that it is worth while to examine his house and to overhaul his heating equipment. Weather strips, double windows, pipe coverings, clean flues and chimneys, and tight fittings in ash-pit, doors, dampers and furnace parts will all pay. Damper control is one of the chief secrets of economical heating. Clean surfaces are most essential, as soot is a poorer conductor of heat than asbestos, Care, attention, and taking pains will be the greatest factors in saving domestic coal.

The Steam Plant Fireman

"The fireman is, however, the biggest single factor to be considered in a campaign to secure the largest saving of coal. Many manufacturers have made a serious mistake in failing to consider the fireman as a skilled worker. Too often he is treated as a roustabout. He is not well instructed nor given proper labor saving devices. As coal increases in price, or becomes difficult to get, the fireman handles more and more of his employer's money. His efficiency means more in dollars and cents. This is an encouraging feature in the situation. It means a better recognition of the importance of the fireman, more efficient work on his part, and a consequent increased saving of coal. The viewpoint is changing. It is no longer cheaper to pay for the coal than to educate the firemen.

"In carrying out a campaign to promote the saving of coal, let the appeal be made to the householder to cut down his consumption in every way possible, but above all, give serious consideration to methods by which a systematic relationship may be established between the office and the fireman. Encourage the manufacturer to take a keener interest in his fuel consumption and to back up his fireman by giving him the best information and equipment available. This problem has two phases: first, to arouse the interest of the manufacturer and his engineer and fireman, and to point out the part which they can play in relieving the present crisis in coal supply; second, to furnish whatever technical instruction may be desirable and which may be immediately applicable to accomlish the result sought."

BOILER FAILURE DUE TO INCRUSTATION

THE formation of a hard boiler incrustation, consisting largely of silicates, was the apparent cause of a peculiar boiler failure, which was reported on recently in the "Chemiker Zeitung."

A series of boilers had for some years been installed in some works, and the boilers, which were in uninterrupted use, had been cleaned every three months. Under the pressure of work the cleaning had to take place at intervals of four or five months; then a crack developed in one of the boilers; the boiler was quickly repaired without much inquiry into the cause of failure, and then a second boiler failed, exactly in the corresponding spot. The boilers, which were combined with superheaters, were provided with two internal flues, which were corrugated in the front part; the cracks occurred in the straight flue near the corrugation. The examination proved that the iron was sound, but that the incrustation was locally abundant and of unusual composition.

Ten samples were taken of the deposit, which was hard in some parts and muddy near the superheater end, and which varied locally in composition to an extraordinary degree. The carbonates were always low, about 1 per cent.; the lime (CaO) percentage ranged from 1 up to 24, the magnesia (MgO) percentage from 2.7 to 25, the calcium sulphate from 2 per cent., up to 83 per cent., the silica

(SiO_2) from 9 per cent. to 59 per cent., and the percentage of iron and aluminum oxides (together) from 0.2 to 59. The iron did not come from the water, but from the boiler plates, which were corroded near the superheater end. The silica percentage was high in general, highest in the muddy portion.

The hard scale, which seemed to be responsible for the local superheating and cracking of the plates, contained 36 per cent. of SiO_2, 2.4 per cent. of iron and aluminum oxide, 20 per cent. of CaO, 8.3 per cent. of MgO, 48 per cent. of $CaSO_4$, and had also a high percentage (6) of water of hydration. The feed water came from two sources, one of which was rich in silica; such feed water is not worth chemical softening sometimes, but may be used when the boilers are frequently cleaned. A further study on silicate boiler scales is to follow.

GRAPHITE LUBRICATION

IN a paper contributed to the Journal of the American Society of Mechanical Engineers, C. H. Bierbaum states that in 1913 some 30,000 tons of graphite were used for lubrication purposes. He states that both natural and artificial graphites commonly contain impurities in the shape of very hard abrasive materials, the effect of which he demonstrated by using a wooden lap fixed on the end of a high-speed shaft and coated with the graphite to be tested. On applying a glass slip to this rapidly revolving lap the scratches produced by the impurities could be easily seen on examining them through the microscope, using oblique illumination. In the paper a number of micrographs are given showing the results obtained. With thoroughly purified graphite there is no abrasion.

To obtain permanent suspension of graphite in oils or the like the particles of graphite must be less than one two-hundred-thousandth of an inch in diameter, and the oil must be free from acid or from any tendency to form acids by turning rancid. The author maintains that the use of these permanent suspensions of graphite is, however, undesirable, holding that with larger particles than are necessary for permanency of the suspension, the graphite is more effective as a lubricant. His view is that if the particles are large they will be caught and retained between the opposing surfaces of a bearing, should these approach near to each other owing to a failure of the oil film; whilst under similar conditions he asserts particles of the size necessary for forming a permanent colloidal suspension of the graphite would prove ineffective. The point, however, is obviously one to be settled by actual practical experience and not on a purely theoretical basis, and users of these colloidal suspensions do make the claim that, whatever the mechanism at work, their lubricated surfaces do, as a matter of fact, get loaded with graphite, notwithstanding the smallness of the particles.

STEAM VERSUS DIESEL

AN American sea-going engineer with first-hand knowledge of the service of both types says that while the modern steam engine is a wonderful machine, the Diesel motor is still more wonderful. The manual labor of handling the fuel is done away with altogether. Once the motor is started the fuel supply is kept up by pumps on the engine itself, delivered to the filter and from there to the cylinders, where combustion takes place. After it has done its work in the cylinders it passes off as waste gas to the atmosphere. All this takes place without manual labor, and to the engineer who has been with steam engines and then takes up the Diesel, the change appeals most forcibly, for with the machine developing its power within itself all that is necessary is the occasional manipulation of a valve. It is true, this engineer admits, that the Diesel has not yet reached the state of perfection at which the reciprocating steam engine has arrived, but considering the shortness of the time it has been employed in marine work, that could hardly be expected. There is not the slightest doubt, however, that in a few years' time it will be, in respect of reliability, in advance of the steam engine. At present there are motorships crossing the Atlantic with as great regularity as steamships, keeping as good, if not better, time, and coming through the heavy weather without a hitch. "I have," the writer declares, "spent a good few years on the Atlantic, and I would rather be with a Diesel engine in heavy weather than with a steam job."—Syren and Shipping.

REGARDING PACKINGS, WORN THREADS AND OTHER ENGINE ROOM PROBLEMS

By J. M.

IN the general attempt to keep down engine room expenses, there has been considerable temptation to engineers to, for some purposes, save their higher priced packings and use lower priced materials of a different kind instead. In the lower pressures this is quite feasible so far as packing for flanges, cylinder heads, low pressure pumps are concerned, but for piston rods, mudports and manholes, I, for one, do not favor this low-priced material. Incidentally, I might mention an instance that came to my notice some years ago, where the use of unsuitable materials as a substitute for the "dollar a pound" patent piston packing formerly used resulted in so cutting and scoring the rod and in producing undue friction as to many times more than offset the difference in cost of material used. The loss was really due to the new supply of proper packing not being on hand until some time after the old supply had been exhausted, rather than by intentional experiment on the part of the attendant. Speaking first of plants using the lower pressures, say 80 pounds and under. In one of these equipments the only packing that has been used on the cylinder heads during the last few years has been candle wicking, bought then at ten cents per ball. The method of procedure is: Remove the cylinder head and around the portion of it which normally projects into the cylinder, wind two laps of the wicking close together and close to the shoulder, then wind a third lap on top of these two, taking care not to wind it so tight as to spread the first two laps, thus drawing the third one down between them. The wicking is cut long enough that one end can be passed out through one bolt hole of the cover and the other end carried so as to give a little more than the exact three laps and then pass out through another bolt hole. This holds the ends in position while the head is being returned to place. The threads of the bolts, if they touch the wicking are more inclined to abrade it than to pull it out of place. When drawn up tight this packing does not take up much space and therefore does not materially increase the clearance space. As stated before, it is O.K. for pressures of 80 lbs. or less. This method has been used successfully on an engine fed from a boiler carrying over a hundred pounds pressure. For flanges and for covers of rectangular steamchests, I have found asbestos board both cheap and serviceable. Sheets one-sixteenth of an inch thick are suitable if the joint surfaces are smooth, but pitted or corroded joints may require two ply of this, or one ply of eighth inch board. Asbestos yarn is another material in considerable favor by a few engineers. My first acquaintance with this kink was when calling on a friend some years ago. He told me he had packed the steamchest cover just a few days before and used only asbestos yarn, putting one lap around inside (I think he said inside) of the bolts, and afterwards winding a short piece around each bolt. He used one piece to each bolt and each piece around its bolt once. There was no sign of a leak at the time of my visit, and if I remember rightly, he was carrying something over a hundred pounds pressure on his boiler. The outfit was a comparatively small one, but the said steamchest cover would measure at least 15 x 20 in., and I think 18 x 24 is more nearly its real dimension, consequently the saving in sheet packing was noticeable. My next lesson in this line came about seven years ago. I went over to the machine shop to get a couple of stud bolts made and meanwhile the engineer in charge packed one of the steamchest covers with the asbestos yarn, placing it inside the bolts and lapping the bolts with short pieces as mentioned above. The pressure carried on the boiler was 110 lbs. That joint gave no further trouble that season, and I have questioned the men in charge since, and so far have not learned of that particular joint having ever been packed since. The outfit, however, seldom ran more than six or seven months in each year. After seeing these two successful applications of the scheme I tried asbestos yarn myself, but prefer the asbestos board instead, as I general-

FIVE TALENTS OR ONE?

DURING the early months of war, many students of historical events drew inspiration from the saying that "history repeats itself," and on every hand one heard forecast after forecast which were all in turn completely upset as each phase of Armageddon unfolded itself to the world's inhabitants. At least one parallel drawn by a writer has been justified by the course of events. He drew attention to the fact, and it has not so far been contradicted, that at the close of the Napoleonic wars, the world was really more civilized, judged from the standpoint of intellectual knowledge and industrial achievement than it was at the beginning of those troublous times. Numerous advances in the arts and sciences, manufacturing developments, and political economy took place, which marked great progress at the time and formed a solid foundation for that phenomenal development of the British nation, the envy of which is not the least of the present war's causes.

Now that the threatened avalanche of militarism has been definitely averted, and seems in a fair way of being rendered harmless, the strain of recent events has found expression in many ways, not the least valuable of which is that of "self-search" as typified by some recently published books by authoritative writers. We refer specifically to the book "Eclipse or Empire," by H. B. Gray and S. Turner. The theme of this book is the subserviency of everything to the industrial national aspect. Extracts received from an English contemporary indicate the exceedingly chastened spirit in which the authors view the industrial placidity of the British nation during the past two or three decades. They state "that during the last twenty to forty years most of the inventions, new ideas and developments have been given to the world by countries other than our own; furthermore, that their value has been more quickly appreciated and put to practical use in foreign lands." As our authority expresses it, "the book, condensed to the point of extreme brevity, is a valuable resumé of alleged national shortcomings, and should be in the hands of every engineer; indeed, just such a compilation, cataloguing and digesting for easy reference a survey of the entire industrial field from one viewpoint was badly needed.

The burden of the foregoing remarks in their bearing on our past, present and future development is sufficiently obvious. We were not able, nor did circumstances give us the opportunity, to benefit industrially, at the time, by events of a hundred years ago, but now every force at the service of mankind is directly engaged in military, industrial and scientific activity, the results of which are, so to speak, immediately at our disposal.

True, the return of peace will see the re-entrance of our present enemies, under due limitations no doubt, into the world's industrial arena, but what of the present? Is the cessation of hostilities to find us where we were at the start? Shall we lack interest for the present, and avoid effort in the future to avail ourselves of the world's advance marked in years instead of decades or centuries as formerly? Amidst the wealth of information being spread almost daily, are we to find no atoms which we may retain and benefit thereby? Shall our record in the present forceful era be one of assimilation only, or one of forceful origination. The future alone can tell, but the making of the answer is in the hands of our manufacturers now. They are in the position of the talent receivers—the point is whether they wish to be known as the man who received five talents and doubled them, or the man who received one—and "hung on to it."

To quote from the work which prompts these remarks "It matters but little what a man is to-day—the great matter is what he desires and intends to be in one, or two, or three years' time. He is not a mere machine with two hands and two feet—but a living pulsating energy. He has a trinity of powers—spirit, mind and hand, and the least of these three is hand. For it is only the spirit to do, and the mind to create, that can make the hand move at all. . . . The progress of our nation will depend on the rate at which we turn the principles and theories of science into terms of ascertained facts."

The Operators' Point of View

DOES A PISTON STOP AT REVERSAL?

AS a connecting rod is not of "infinite length," I think Mr. Miller's argument falls down from the fact that, to arrive at his conclusion, he has to introduce a proposition that is impossible. The piston travels fastest as the crank is at right angles with the piston and slows down as it approaches the direct horizontal, and again is accelerated as the opposite angle is approached. At the centre as the piston reverses its motion it must stop to make the return trip.

Also, if therefore the speed of the piston varies during each stroke, while the flywheel is in constant and uniform motion, it is not beyond the possible that at the moment of reverse motion the piston could and does stop.

W. K. MACLEOD.

Chilliwack, B.C.

HAVE read with interest Mr. Schaphorst's article under above caption. I have heard this subject argued many times and it recalls an incident that happened some years ago. The local freight had pulled into the depot. The engineer was a man who would accept no signal not properly and clearly given. It was desired to spot a certain car for unloading at the freight shed and the engineer was moving ahead slowly on the brakeman's signal. The brakeman, engaged in conversation with the station agent, allowed the car to pass the spot where it was desired to have it stop and seeing his error gave the signal to back up, but the engineer continued to move ahead. The brakeman then ran ahead and demanded why the engineer was still moving ahead and the reply was coolly given. "In order to back up I must first have a signal to stop as I cannot back up while going ahead without stopping first." This seems to be a single answer to the crosshead and piston problem.

Is not also the crosshead somewhat analogous to the alternating electric current sine wave. Using the clock diagram for the development of the sine curve the e.m.f. begins at zero, rises to maximum value at 90 deg., falls again to zero, rises again to maximum value in the opposite direction at 270 deg., and falls again to zero, thus completing one cycle, or, in the case of the crosshead, one forward and one backward stroke completing a revolution of the shaft.

St. Thomas, Ont.

THINGS ANYBODY CAN DO?

By D. A. Hampson.

BUILDING a fire in the forge and dressing an emery wheel! Anybody can do those things, you say—and yet if you come right down to the fine point, few mechanics can do these homely but important tasks well.

Building the Forge Fire

While any man can build a fire of some sort, not every one can build a forge fire in a room occupied by other workmen without almost smoking them out. Following the few simple rules will make this easy. To begin with, scoop out the coal over the tuyers down to the lining of the forge or to the pan itself if it is unlined, making a pocket that will just about hold a double handful of shavings. More shavings than this are unnecessary. If shavings are not available, use excelsior wadded into about the same size. Waste will do in a pinch, but is open to several objections, principal of which are the odor from burning, greasy cotton, and the loss of expensive material, for in these days it pays to have waste washed.

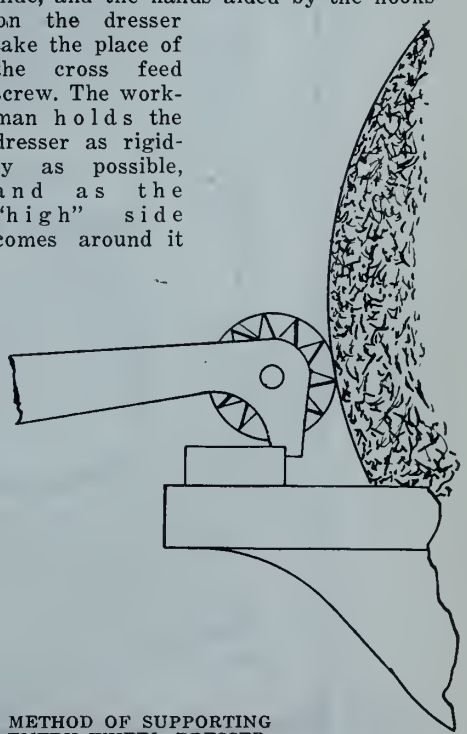
The pocket made in the dead coal is better than scraping the coal all away, for it starts the fire in compact form and prevents many a lost start. As soon as the shavings are lighted, begin to throw on pieces of coal that have once burned—not fresh coal or clinkers—and turn on the blast gently. If the blast is started too hard, the shavings will burn so quickly that the coal does not get a chance to ignite; what is wanted is just enough air to keep the fire going and furnish free, smokeless combustion for the shavings, but at the same time, to burn slow enough to give the coal a chance to "catch." Following the flame with a light covering of coal—not too much in the middle—will produce in less time than it takes to tell it, a small but live fire that may be enlarged if it is so desired. And the best part of it is that the trick could be turned in your own parlor without creating any smoke that you could notice.

Dressing the Emery Wheel

It is hard to impress upon the minds of many mechanics the fact that the wheel on which they sharpen their tools must in turn be sharpened and have the nicks taken out of it. Not many jobbing shops possess a diamond, but they all have one or more emery wheel dressers around somewhere, that use fluted or star wheels, or cutters. These wheels present a broken area of contact to the emery wheel or grindstone and as they revolve with the latter, they cannot slide along and fill or glaze as does the work being ground. As they revolve, the hardened points cut or break up the surface of the grinding wheel, thus exposing new, sharp grains for working. A few passes across a grindstone or emery wheel will do this sharpening.

But through the carelessness of workmen the face of grinding wheels gets grooved and dug up, and, worse still, they get flat spots worn on them producing what appears like a wheel out of round. To restore the wheel to a round again requires something more than following across with the dresser. The high side must be turned off and the process is similar to a like job in the lathe, but the tools used are the dresser and the work rest of the machine; in case the latter is of odd shape, a bar of steel and two C-clamps will answer.

The drawing shows how the work is done. The dresser is the cutting tool, the bar of steel corresponds to the cross slide, and the hands aided by the hooks on the dresser take the place of the cross feed screw. The workman holds the dresser as rigidly as possible, and as the "high" side comes around it



METHOD OF SUPPORTING EMERY WHEEL DRESSER.

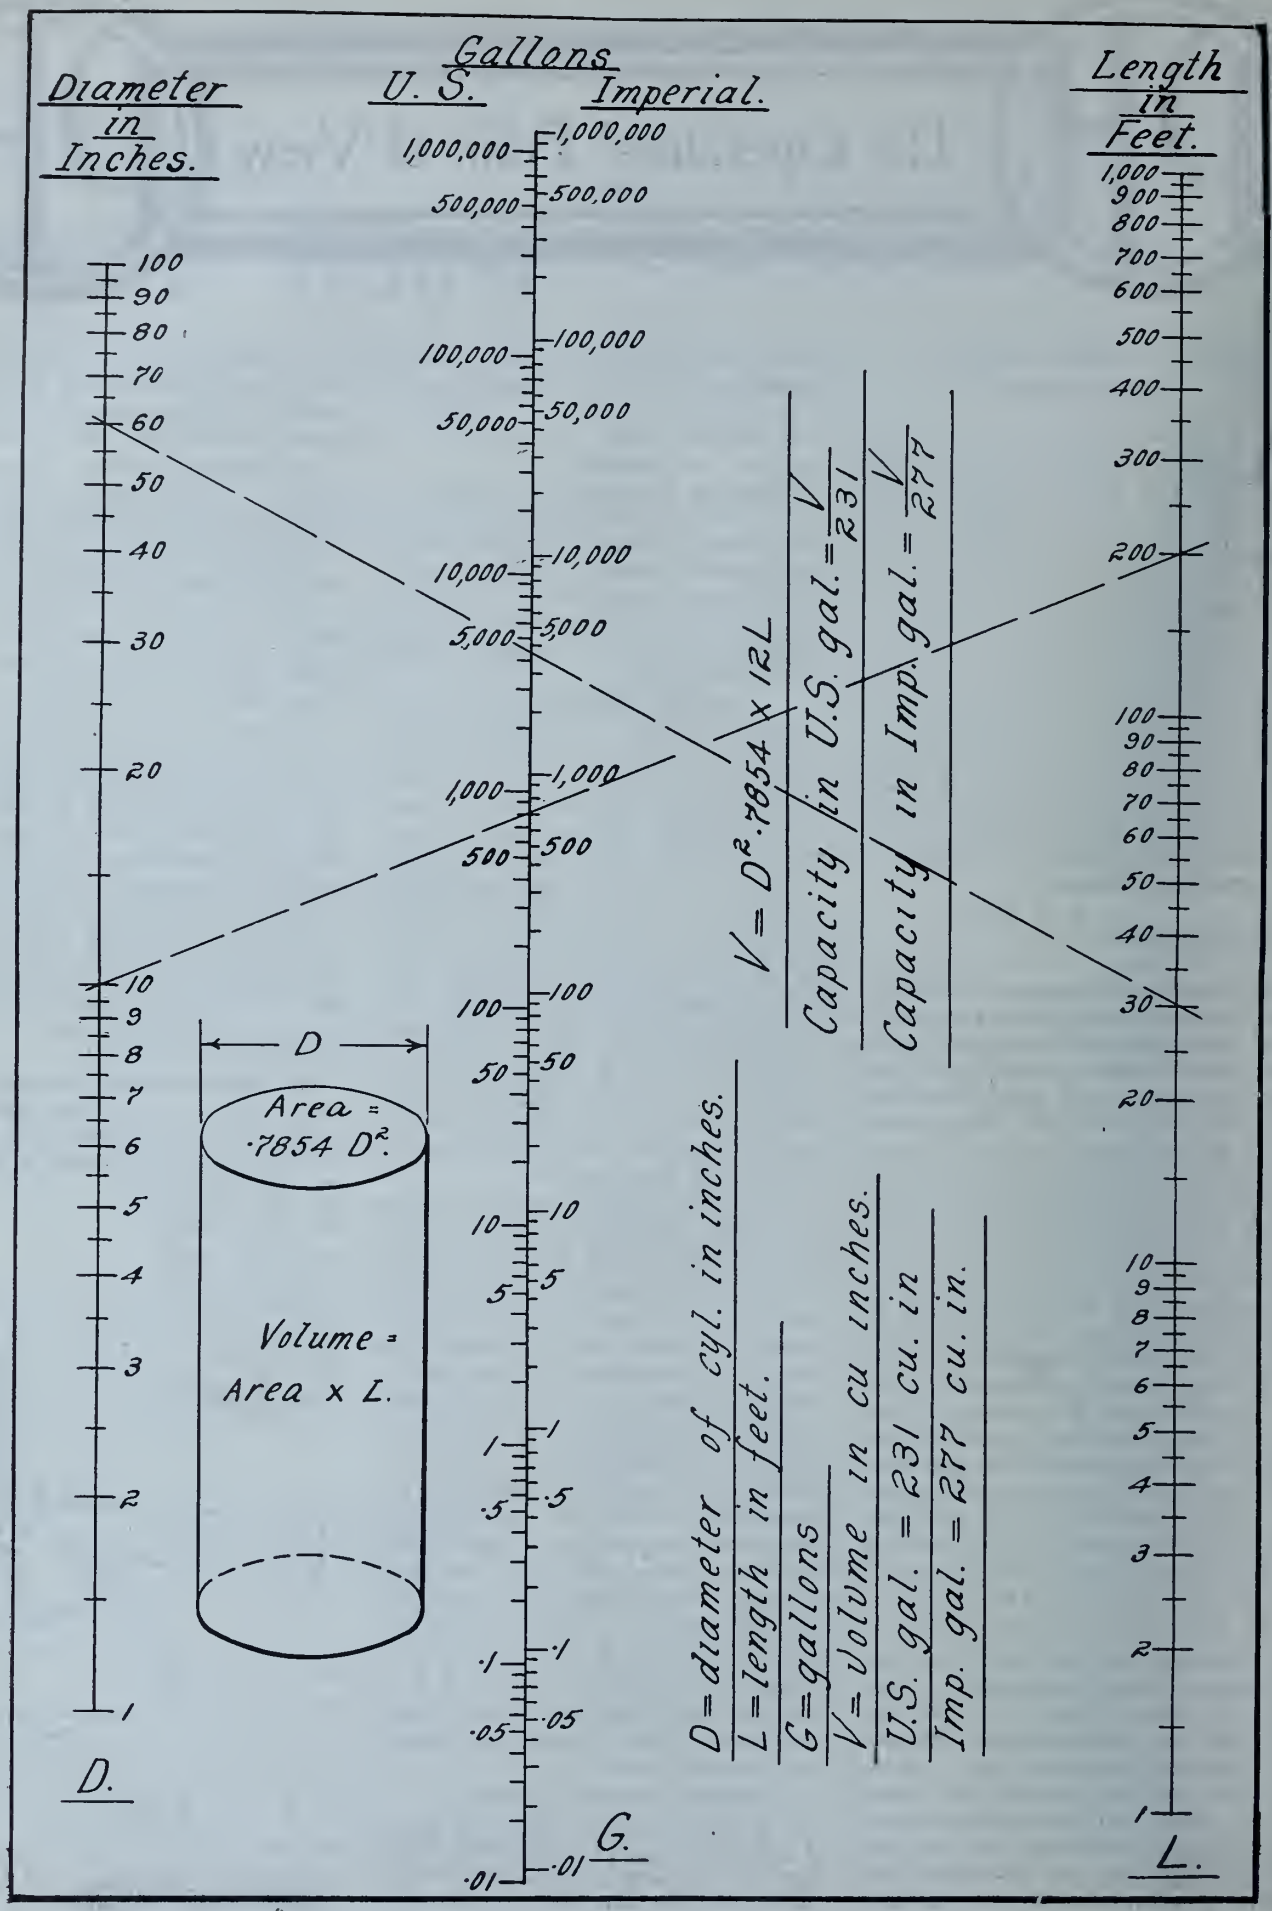


CHART OF CYLINDRICAL TANK CAPACITIES.

is cut down, each revolution taking a little more. In doing this, the work is started on that part of the wheel that is largest in diameter and a cross movement imparted to the dresser so it doesn't cut grooves in the wheel just as would a piece of work held in one place. Keeping up this cross movement with the handle of the dresser held fixedly in one place and gradually raising it, will cut the stone down to a true cylinder. But it takes care and it couldn't be done except from the steadying provided by the hooks on the dresser.

CAPACITY OF CYLINDRICAL TANKS

CALCULATIONS for the capacity of cylindrical vessels are often tedious work to those not very familiar with the method by which these results are attained. While many handbooks can be had that give the tables for the various capacities for certain diameters, it is invariably the case that the time occupied in securing the desired information is greater than would be required to figure it out. It is well, therefore, to learn the principle by which these mental problems are solved. Generally speaking the capacity of a vessel is computed in gallons, while the dimensions are invariably given in feet or inches, and it is, therefore, necessary to determine the volume of the interior and find the corresponding capacity for such a volume. The volume of a cylindrical vessel is found by multiplying the area of the base by the length or height. The area is .7854 times the square of the diameter; for instance, it is desired to find the volume of a cylindrical tank 15 feet in diameter and one foot deep. The area of the base would be $.7854 \times D^2 = .7854 \times 15 \times 15 = 176.7$ sq. ft., and one foot in height would give a volume of 176.7 cu. ft. One cubic foot of water contains 6.23 Imperial gallons or 7.48 U.S. gallons; therefore the capacity of the above tank in Imperial gallons would be $6.23 \times 176.7 = 1100.8$ Imp. gallons. In United States measure the capacity would be $7.48 \times 176.7 = 1321.716$ U.S. gal. In smaller tanks where the diameter is usually given in inches and the respective volumes of an Imperial and U.S. gallon are 277 and 231 cu. inches, it is customary to use these latter values in calculations.

A cylindrical tank 60 inches in diameter and 30 feet long would have a volume of $.7854 \times D^2 \times L = .7854 \times 60 \times 60 \times 30 \times 12 = 1{,}017{,}878$ cubic inches. The capacity in English measure would be $1{,}017{,}878 \div 277 = 3674$ Imp. gal. In U.S. gal. the capacity would be $1{,}017{,}878 \div 231 = 4406$ gal.

To convert Imperial gallons to United States gallons multiply by 1.2; thus, in the above example $3674 \times 1.2 = 4408$ U.S. gal. To convert U.S. to Imperial multiply by .833.

$4406 \times .833 = 3671$ Imp gal. The small differences in the values result from the slight error in decreasing the number of decimal places in the constants 1.2 and .833. These constants are derived from dividing the respective volumes by each other; as 277 divided by 231 gives 1.199, and 231 divided by 277 gives .833.

It is often possible that an approximate value is sufficiently accurate for tank capacities, and for this purpose the accompanying chart will be found of great service. On the graduated scale D, to the left, are given the various diameters of tanks in inches, and in the right-hand column L the length in feet. A straight line drawn from any two points on the two outer scales will interest the middle column G at the approximate capacity in U.S. and Imperial gallons.

IS WHITE PAINTED PIPE COVERING MORE EFFICIENT THAN BLACK?

By A. H. W.

THE consulting engineer of the plant of which I have charge tells me that by painting the pipe covering dark I lose a great deal more heat than I would had I left them white. He also says that stove pipes which have been painted white will not let any heat out in the room, whereas, if they are painted black, they will let out considerable heat.

An explanation of these points will be much appreciated by the writer.

The fact that a perfectly black body will absorb more heat than a lighter colored body must be accepted as a phenomenon which we cannot definitely explain. We unconsciously apply this knowledge in everyday life by donning light colored apparel for summer rather than dark, the better to shed the heat of the sun's rays.

This relation between the heat absorbing power of a body and its power to reflect light is accounted for by considering both light and heat as a form of radiant energy, differing in the way in which they affect our physical senses. We see a body by reason of light reflected from that body to the eye. Were it possible to find a body which would absorb all light and reflect none, it would appear perfectly black. Again, we are sensible to the heat of a body by reason of heat reflected from the body. A perfect absorber of heat would reflect no heat radiation.

It so happens that bodies which have the properties of absorbing light most readily are also the best absorbers of heat so that a perfectly black body has the highest heat absorbing power. Conversely those bodies which are the best reflectors of light have the least heat absorbing power. The same applying relatively to all intermediate conditions between light and darkness.

Although no such perfectly black body is known, yet a surface coated with lamp black absorbs such a large proportion of heat and light radiation as to sufficiently fill the condition for practical purposes. Taking the heat absorbing power of lamp black as 100%, it has been found experimentally that the relative heat absorbing power of white lead is about 20%, with that of burnished silver the lowest at 7%. It would be interesting in this connection to know the value for aluminum paint which is sometimes used on stove pipes, but no figures for this are available.

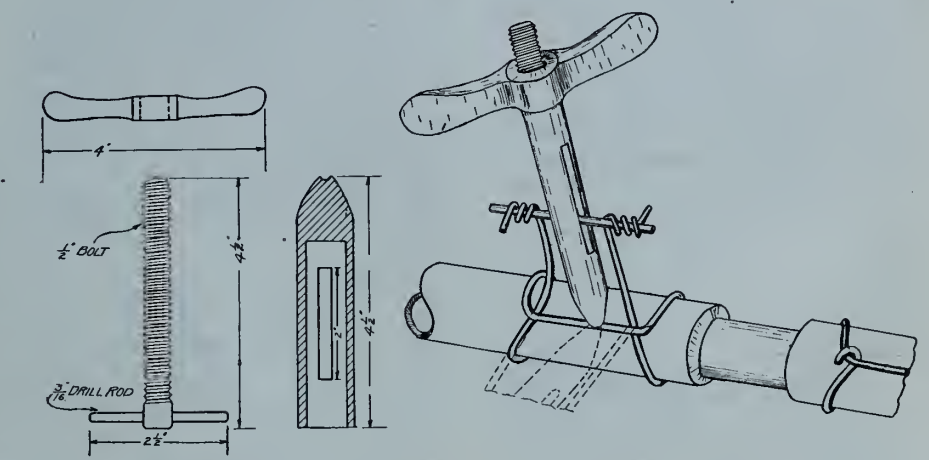
However, this should answer your query as to the possibility of preventing in some degree the loss of heat by painting the radiating surfaces white, though the ideal condition referred to in your letter will hardly be attained.

WIRE CLAMP MACHINE

By Sam E. Burd.

OWING to the large number of hoses in use at our plant, I devised the machine shown in the sketch to save time and clamps, and I find it will hold nipples, etc., better or as good as bought clamps, and it is a lot faster.

I use annealed wire ⅛ in. in diameter, wrap it about the joint as shown, set the nose of the tool against the wire as shown, wind the loose ends around the pin and screw up tail nut. When tight, throw machine so as to make a hitch on the wire and cut.



DETAILS AND ARRANGEMENT OF WIRE CLAMPING DEVICE.

A WATER LEVEL GAUGE

By J. E. McCormack.

I HAVE worked in several small mills built for ore crushing and washing. Tanks were always provided at a point higher than the jigs, vibrators, etc.,

using the water. The pump man was warned by whistle signals when the tank was nearly full or nearly empty. I have had to depend on unsatisfactory floating tank gauges until I became disgusted with such contrivances. Now, however, until someone shows me a better gauge, as easily constructed and as visible for

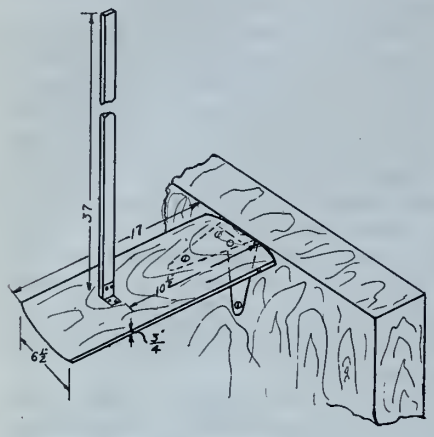


FIG. 1.

reading from a distance as is the one described below, I shall choose it for use in such plants whenever my personal convenience is involved.

The float shown in Figs. 1 and 2 is a piece from the centre of a thick barrel head. Its dimensions are: Thickness, ¾ in.; extreme length, 17 in.; width, 6½ in. The upright piece is 1 in. wide, ½ in. thick, and 37 in. long, and is placed at right angles to the float, with its 1 in. way parallel with the long way of the float. The centre of its secured end is 10½ in. away from the end of the float to which the hinge is attached. The hinge used is 13 in. long when open, has the joint midway of its length, and is 2¼ in. wide at the joint. Referring to Figs. 3 and 4, with the water level 7 in. below the joint of the hinge the top of the upright piece rests on the edge of the tank, but with the water level 4½ in. below the joint of the hinge the upright piece assumes an almost vertical position and is, therefore, visible for some distance.

In tanks 3 to 5 ft. deep (and quite pos-

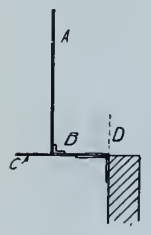

FIG. 2.

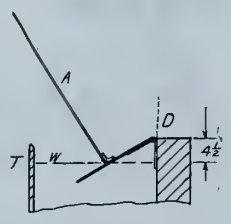

FIG. 3.

sibly in deeper ones also) a larger float with a longer upright piece and placed nearer the bottom gives visible warning when the water has fallen below the predetermined point for which it was set. This lower float must have its upright located by experiment owing to the action of the water on it.

Small differently-colored flags attached to each upright increase the distance from which the gauges may be read. Bell circuit push buttons may be located when these uprights may come against them and give audible warning in the engine room if desired, but this is not necessary unless the view is obstructed. These gauges are sufficient where the pump man is warned by whistle, as in construction work and ore crushing mills, etc.; and if the hinge is a free working one, the device does not cramp, bind or stick, nor get out of place, as did various devices previously tried out.

A FUSIBLE PLUG FOR BOILERS

By James E. Noble.

WHEN given reasonable attention the fusible plug is an important safety device. When the filling becomes covered with scale its usefulness as a safety device is nil; therefore, it should be cleaned off frequently.

Banca tin makes a reliable filler, but no filler will remain in its virgin condition very long when installed in a working steam boiler. It should be refilled with fresh tin about twice a year.

When careless attendants are in charge the fusible plug is apt to be neglected and its usefulness destroyed, but if it is in anything like fair condition it will protect the boiler from the carelessness of an attendant who may allow the water to reach a dangerously low level. The attention of the operator will be directed to the racket kicked up by the escaping steam and the necessity of emptying the boiler to instal another plug.

The manager, chief, or owner should personally see that a proper filling is put in, for many cases are on record where the attendant has refilled a plug with an iron core instead of a tin one.

On return tubular boilers the plug is usually placed two or three inches above the top row of tubes in the back head. A coating of graphite is usually placed upon the plug thread before inserting it into position, so that it can be removed at any future time with ease.

The sketch illustrates how one engineer installed fusible plugs with what

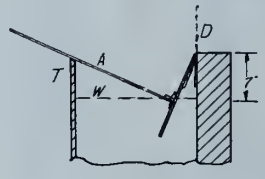

FIG. 4.

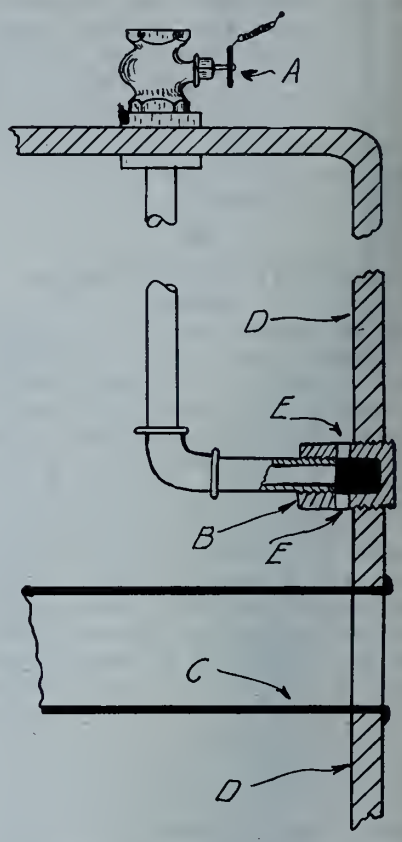
he claimed satisfactory results. His idea was to have the plug so inserted that he would not have to shut down if one melted out.

The hollow cap B was screwed into the tube sheet D. The cap was filled with Banca tin and there were openings into the steam space at E E. C is one of the boiler tubes. If the plug melted it would run out at E and steam would blow from the valve A, to which a small steam whistle was attached.

This called attention to the danger, and if the water was not below the col-



FUSIBLE PLUG ATTACHMENT.

umn, the cock could be closed until evening, when the boiler could be blown down and a new plug inserted.

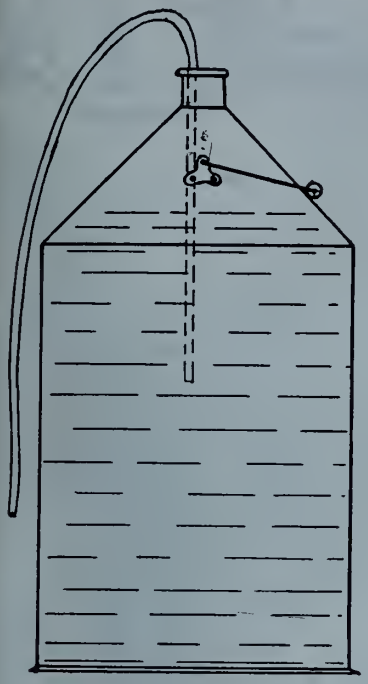
SIPHONING GASOLINE AND SIMILAR LIQUIDS

By J. M., Haliburton

ATTEMPTING to pour from a full can of the five gallon type and finding it very difficult to obtain an even flow without the liquid running down the side and dripping on to the floor, I took a piece of rubber tubing (a piece of any small pliable airtight hose may be used) and holding it by extreme end as in sketch, lowered it into the can as far as convenient, and after allowing it to remain a moment to insure its filling properly, placed my finger over the exposed end and withdrew the tubing sufficiently to allow its outer end to hang below the surface level of the contents of the can, when, upon removal of my finger from the end of the tube, I obtained a satisfactory siphon action, and have frequently used the device since with excellent results.

To change the stream to a second vessel the flow may be momentarily stopped by again placing the index finger over the end of the tubing, or better yet, if the tubing is soft enough it may be closed by squeezing between the thumb and finger.

A suitable strainer may be added to the inner end if desired and with a long enough piece of tubing the vessel, if in an elevated position, may be nearly emptied with this device alone, but in this case if the liquid is low in the can it is better when withdrawing to squeeze the tubing shut between its dry and its



SHOWING TUBE IN ACTION.

wetted portion thus guarding against the entrapping of the air which is in its unsubmerged portion as this might impair the efficiency of the siphon.

The method affords an easy way to draw off a little gasoline from the auto tank when required for priming or other purposes and is more pleasant than starting the siphon by drawing the gaso-

STARTING SIPHON PIPE.

line through with one's breath as I have seen done.

For tubing I have used ⅜-in. eclipse tubing with success where coal oil or gasoline were the liquids involved.

EFFICIENCY TEST ON WATER-TUBE BOILER FITTED WITH MECHANICAL STOKERS

THE following data were obtained during a recent test on a 600 horse-power water-tube boiler of the Heine type fitted with Galt sprinkler stokers:

General.	
1—Duration	8 hours
2—Heating surface of boiler (Heine—600 H.P.)	6,000 sq. ft.
3—Method of firing	Galt Sprinkler Stoker
4—Area of grate	108 sq. ft.
5—Ratio of heating to grate surface	55.5 to 1
Fuel.	
6—Kind used	(Screenings), 2 parts anthracite to 1 part bituminous
7—Calorific value of fuel as fired	
8—Calorific value of dry fuel	12,500 B.T.U.
9—Percentage of moisture	5%
10—Thickness of fire	3½"
11—Ttotal coal fired (wet)	18,600 lbs.
12—Total coal fired (dry)	17,670 lbs.
13—Coal consumed per hour	2,325 lbs.
14—Coal consumed per square feet of grate per hour	21.5 lbs.
15—Ash, clinker and refuse	2,120 lbs.
16—Percentage of ash, etc., to coal burned	12.4%
17—Total combustible	16,964 lbs.
Steam.	
18—Average pressure by gauge	120 lbs.
19—Saturated steam temperature	350°
Water.	
20—Total evaporated at 162°	151,020 lbs.
21—Evaporated per hour at 162°	18,876 lbs.
22—Total evaporated from and at 212°	166,517 lbs.
23—Evaporated per hour from and at 212°	20,689 lbs.
24—Evaporated per sq. ft. of heating surface per hour at 212°	3.4 lbs.
25—Evaporated per lb. of coal as fired at 162°	8.19 lbs.
26—Evaporated per lb. of dry coal at 162°	8.54 lbs.
27—Evaporated per lb. of coal as fired from and at 212°	8.95 lbs.
28—Evaporated per lb. of dry coal from and at 212°	9.42 lbs.
29—Evaporated per lb. of combustible at 162°	8.9 lbs.
30—Evaporated per lb. of combustible from and at 212°	9.81 lbs.
31—Factor of evaporation	1.096
Draught.	
32—Under grate forced.	
Temperature.	
33—Feed water	162°
Efficiency.	
32—Efficiency of boiler, furnace and grate (100 x item 28 x 970.4) / item 8	73.12%
33—Efficiency of boiler and furnace— (100 x item 30 x 970.4) / Calorific value of 1 lb. combustible.	
Average boiler rating developed per hour	600 H.P.
34—Ten sq. ft. of heating surface—1 H.P.	
34.5 lbs. of water evaporated into steam at 212°—1 H.P.	

REGARDING PACKINGS AND WORN THREADS

(Continued from page 323.)

ly find it more easy to hold in place while putting the joint together again. I have known both tallowed candle wicking and asbestos yarn to each be recommended for packing valve stems. I have tried both. Once with each was enough for me. The one was too hard, and the other wore too quickly. I have tried hemp packing for these and like it better, though I would advocate it because of its cheapness rather than because of exceptional virtues for the purpose mentioned. I use oil on it, as this is more convenient than tallow, and, according to my experience, less apt to produce verdigris. One man got fifteen cents worth of this some eight or more years ago. He has been back and forth between two plants using engines 10 x 12 and 11 x 16 respectively, and using from this for the globe valves in both plants. Last autumn he had a little of it left yet. So far as small outlay for packing is concerned, I believe that the said candle wicking, asbestos yarn or asbestos board and the hemp packing provide an easy means to that end, so far as the cylinder heads, steam-chest covers, pipe flanges and globe valves are concerned. I also believe these to be both feasible and satisfactory in plants working at eighty or less lbs. per sq. in. I know that they can also be used for pressures up to 120 lbs., but let us consider another feature in connection therewith. When using those "gol darned patent packings at one or two dollars a pound," we can put the nuts up to a reasonable strain, then after turning on just a little steam for a while and getting the iron heated through, we can tighten up some more, until finally we have a tight and reliable joint without unduly straining the bolts. On the other hand, if we use low priced, less pliable materials, we must perforce put a greater strain on the bolts to make the material imbed itself into any irregularities in the metal surfaces and in order to hold it in place against the pressure of the steam. This excessive strain, on the bolts means ultimate premature stripping of the threads, and this in turn means either increased depreciation or increased repair costs, whichever way you prefer to figure it. This may easily overbalance any first cost saving made by using the cheaper material in plants using these higher degrees of pressure. It is in heating plants and in those power plants which have had the working pressure materially reduced owing to the advent of the new boiler laws that candle wicking, asbestos and hemp, can perhaps be used to advantage.

Delta, B.C.—The council is considering the installation of an electric pump and pump-house in East Delta. Estimated cost, $12,000.

Operators' Instruction Course

Question.—Why is a vacuum measured in inches?

Answer.—It is customary to speak of a vacuum in terms of inches of mercury instead of lbs. per sq. in. simply because the most convenient and accurate method we have of measuring a vacuum is the mercury tube. It could be measured in feet of water if desired but in this case the gauge would have to be over 30 ft. long. When an ordinary pressure gauge is used to measure vacua, it may be calibrated in lbs. per sq. in. or inches of mercury, but such gauges are always calibrated against a mercury tube as a standard. In a barometer the average height of the mercury column is 30 inches and as mercury weighs 0.49 lbs. per cu. in., this column represents a pressure of .49 multiplied by 30 or 14.7 per sq. in atmospheric pressure. Thus, if the barometer stood 30 in., a vacuum of 26 in. would mean there is an absolute pressure of 4 in. or 4 x .49 lbs. per sq. inch.

* * *

Question.—(1) What is the difference between a Fahrenheit thermometer and a Centigrade thermometer? (2) How do you change from degrees Fah. to degrees Cent?

Answer.—(1) On the Fahrenheit scale the boiling point is marked 212 deg. and the freezing point 32 deg. and the interval between these fixed points is divided into 180 deg. Zero on this scale will be 32 deg. below freezing point. The Centigrade scale has its freezing point marked zero and its boiling point marked 100 deg.

Since 100 Centigrade degrees cover the same range of temperature as 180 Fahrenheit degrees, one centigrade degree is 180-100 or 1 4-5 times as long as one Fahrenheit degree.

(2) In converting temperatures from Fahrenheit to Centigrade or vice versa confusion may be avoided by referring to the temperature as being so many degrees above or below the freezing point of water, which on the Centigrade scale is marked 0 deg. and on the Fahrenheit 32 deg. Thus 60 deg. F. is 28 Fahrenheit degrees above the freezing point and equivalent to 22 x 5-9= 15.5 Centigrade degrees above the freezing point. The given temperature 60 deg. F. then corresponds with 15.5 deg. C.

Conversely, 10 deg. C. is 10 Centigrade degrees above freezing point equivalent to 10x9-5=18 Fahrenheit degrees above the freezing point or corresponds to a total Fahrenheit reading of 18+32=50 deg. F. A temperature of —15 deg. F. is 15+32=47 Fahrenheit degrees below the freezing point, equivalent to 47x5-9 =26.1 Centigrade degrees below the freezing point or —26.1 deg. C.

* * *

Question.—We have been using a single stage double suction centrifugal pump, direct connected to a direct current shunt wound motor, to pump water from a well to a tank mounted on a power. Recently we connected up to draw water from the city mains, but now the motor seems to be working under a heavier load than before. Why is this? Would not the city water pressure help to reduce the load on the motor ?

Answer.—The effect of such a change would be to increase the load on the motor by causing it to raise a larger volume of water in a given time, consequently the tank will be filled in a shorter time than before. Keeping in mind the characteristics of the centrifugal pump, that the pressure generated depends entirely on the speed of the pump and for any constant speed the amount of water delivered will be smaller when working against high pressures than when working against low pressures, it is evident that any condition tending to reduce the pressure at which the pump is working will increase the amount of water pumped and therefore the work done by the motor.

While you fail to state the head worked against we can assume from the description of the installation that the presure worked against is not over 150-foot head and that generated by the pump equal to 200 foot head. Then when working alone there was a net pressure corresponding to a 50-foot head for pushing the water through the pipe, while when working from the city mains, with a pressure say of 50-foot head, there was (200 + 50)—150=100-foot head net pressure which, of course, sent more water through the pipes and gave the motor a proportionately greater amount of work to do.

* * *

Question.—Is there any way of finding the brush polarity on a generator without using a voltmeter?

Answer.—If the generator is supplying electric current to a circuit, about the simplest way to determine the polarity is by means of the compass. Hold the compass over one wire of the circuit and arrange the wire parallel with the compass needle with no current flowing. If, when the current is flowing, the north pole of the compass is deflected to the east, the direction of current is towards the north. If deflected towards the west the current is flowing southwards.

When the generator is not connected in the circuit, a good method is to hold a wire from each terminal a short distance apart in salt water when bubbles will arise from the negative terminal. Care should be taken not to touch the wires together and with the higher voltages to keep them well separated as a short circuit on circuits of 100 volts and over is likely to cause bad burns.

* * *

Question.—A refrigerating room 15 x 30 x 8 ft. high is required to chill 5 tons of meat per day from 80 deg. to 34 deg. F. Provision must be made for 2 16-c.p. inc. lamps and one man working in the room for 8 hours each day as well as one complete change of air per day. The insulation is a 16-inch brick wall and 2 inches of cork.

Answer.—The average specific heat of meat is about 0.75. The amount of heat to be extracted to lower 10,000 pounds from 80 deg. to 34 deg. is 10,000 × (80 —34) × .75 = 10,000 × 46 × .75 = 345,000 B.t.u. (1).

Quantity of air to be cooled is 15 x 30 x 8 = 3600 cubic feet or about 3.6 × 73.1 = 263.1 pounds (73.1 pounds per 1000 cu. ft.). Specific heat is 0.237. Heat to be withdrawn in cooling 263.1 pounds of air from 70 deg. to 34 deg. = 263.1 × .237 × 36 = 2,244.7 B.t.u. (2).

Area of walls = (2 x 30 x 8) + (2 x 15 x 8) + 2 x 15 x 30 = 480+240 + 900 = 1620 sq. ft. With the insulation mentioned the loss of heat is 2.75 B.t.u. per sq. ft. per 24 hours per degree difference between outside and inside temperature. Assuming outside temperature to be 70 deg., the heat loss by radiation is, 1620 × 2.75 × 36 = 160,380 B.t.u. (3).

Two lights require 3.5 × 2 × 16 = 112 watts. Heat per minute = 112 × .0568 = 6.36 B.t.u. per minute or 6.36 × 60 × 8 = 3,019.4 B.t.u. per day (4).

A workman will radiate about 500 B.t.u. per hour or 500 × 8 = 4000 B.t.u. per day. (5).

The sum of these five results represents the total heat to be removed, which equals 345,000 + 2,244.7 + 160,380 + 3,019.4 + 4,000 = 514,644.1 B.t.u. per day. This is equal to $\frac{514,644.1}{288,000}$ = 1.787 tons of refrigeration.

A CONTRAST

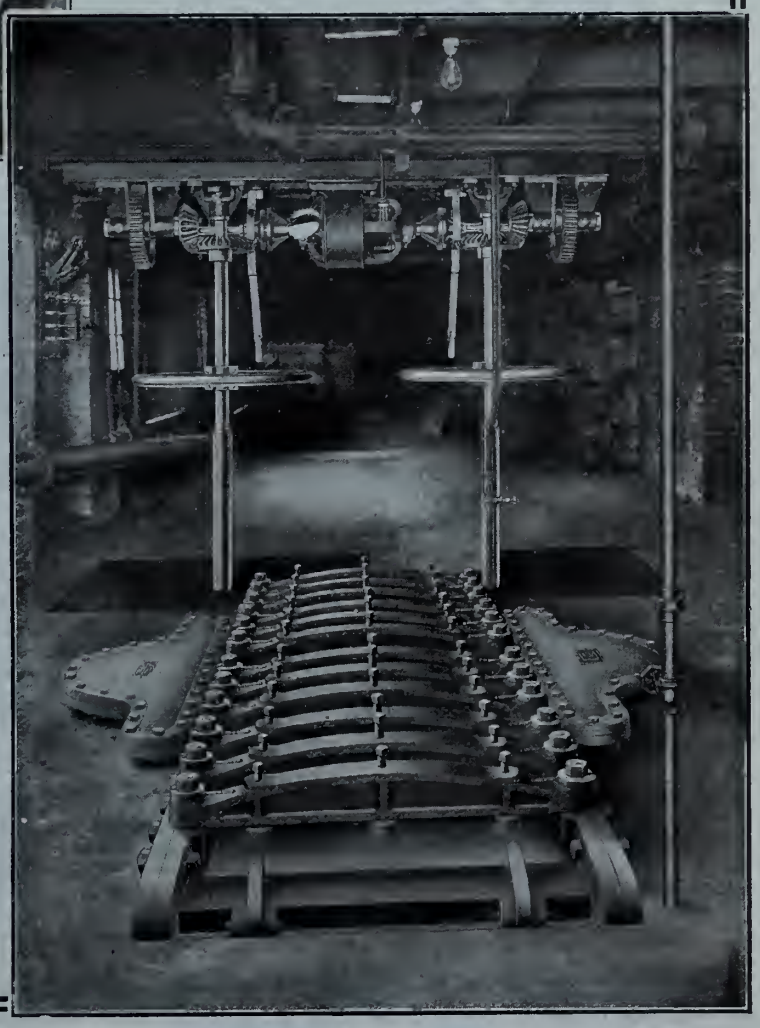
The photograph opposite shows one way of keeping such debris as sticks, leaves, etc., from being drawn into your pumps, condensers and other apparatus.

A diver is engaged periodically to go down under the water to remove the debris that accumulates around the strainer on the inlet of the intake pipe.

The photograph below shows another way of keeping debris from entering your plant via the water intake plan.

A Twin Strainer is used to catch all solids, such as fish, sticks, leaves, twigs, stones, etc., that are carried along in the water. These solids are retained in the baskets of the Strainer, where they can be readily removed at any time without interrupting the flow of water, for when the water is flowing through one set of baskets the other set is out of service.

Motor operated Twin Strainer in 42-inch suction line to condenser—Toledo Railways & Light Company. The motor and operating apparatus is overhead, where it will not be damaged during high water seasons.



Some of the many advantages of the Twin Strainer installation will be readily apparent.

The most obvious one is the convenience of cleaning, which is an assurance against interruptions to the service. The Twin Strainer can be cleaned once or forty times a day, as conditions demand. It can be located in any convenient place inside the plant, where it is accessible at all times.

Twin Strainers will strain water, oil, or any other liquid, and are furnished for either motor or manual operation, in all sizes from 1 to 48 inches inclusive. The basket equipment is varied to suit conditions. Complete information in Bulletin "A." A copy is yours on request.

TEN YEARS AGO AND TODAY

Old style Rotor permanently abandoned seven years ago.

Ten years ago—before we brought our Turbine to its present high degree of perfection—the manufacturing difficulties made it impossible to produce a solid rotor without semi-circular slots. These slots are acknowledged as highly undesirable and built-up rotors are never made with them. We finally invented and patented a process of manufacture whereby we were able to eliminate the slots and today unslotted buckets in solid rotor are AN EXCLUSIVE STURTEVANT FEATURE.

The unslotted bucket is obviously much stronger and permits of a thinner and more efficient vane. Furthermore it is self-evident that the slots encourage leakage from one bucket to the next and this further reduces the efficiency.

The unslotted bucket is just one of the superiorities of the Sturtevant steam turbine. The other advantages are given in detail in our catalogs 209 and 210, copies of which will be sent on request.

Improved Sturtevant Rotor—Cannot be duplicated due to patents.

Sturtevant

This trap can be installed in any position desired as it has two outlets.

This is a remark very often made by users in reference to—

The LONG Patent Steam Trap

Has But One Movable Part

Valve is actuated by the expanding and contracting of a tube, a motion that is positive and of sufficient force to close the valve against a pressure of two hundred pounds.

The Long Trap is automatic and requires no valves except those which control admission of steam to apparatus to which trap is attached. It is capable of draining from 900 to 1,500 feet of one-inch pipe.

There are other superior points about the Long Steam Trap. as it could be used as a condenser for heating water for washing bottles, etc., and still remain a trap. Let us tell you the complete story of this wonderfully successful power house facility.

Write.

TRADE GOSSIP

The Winnipeg Tool & Forging Co., Winnipeg, Man., is being reorganized. The company manufacture a line of mechanical tools, mason's tools and wrecking bars, etc.

New Rapid Tanning Process.—An Australian says he has discovered a new rapid tanning process with which sole leather can be tanned in seven days, calfskins in six hours, and other skins proportionately quickly.

U. S. Steel Orders Decrease.—Unfilled orders of the United States Steel Corporation on October 31 last were 9,009,675 tons, according to the monthly report issued. This is a decrease of 823,802 tons from the orders of September 29, and is the sixth successive monthly decrease.

All U.S. Lake Boats for the Atlantic.—A report from Sault Ste. Marie, Mich., states that it was recently announced by a prominent official of the United States Engineering Department that all Government boats now in northern waters are to be withdrawn immediately and placed in the Atlantic service.

Mineral Production in N.B.—During the calendar year 1916, New Brunswick produced $878,446 worth of minerals. The coal values aggregated $367,041, against $309,612 in 1915 and $241,075 in 1914. New Brunswick produced in 1916, 610,118 thousand cubic feet of natural gas, valued at $79,628. The production of petroleum in the province last year was 1,345 barrels, as against 1,020 in 1915.

U. S. Build 8,000-Ton Vessels.—The American International Corporation has received an order from the Emergency Fleet Corporation for seventy 8,000-ton vessels, to be built within one year of the completion of its plant at Hog Island. This is in addition to the previous order for fifty 7,500-ton vessels. The new contract involves about $100,000,000. The Hog Island plant is scheduled to be finished on December 1.

The Canadian Link-Belt Co. announces its ability to again furnish "Link-Belt" mono-rail electric hoists for quick shipment. These machines are made at the Philadelphia plant, where a large additional building is rapidly nearing completion and the already excellent manufacturing facilities are being greatly increased. Both types C-1 and C-2 can be furnished, the safe lifting capacities ranging from 1,000 lbs. to 6,000 lbs. They can be adapted for either direct or alternating current and fitted with plain hand-geared cord operated motor, or a cage operated motor trolley.

Montreal, Que.—The first deliveries on the Canadian Government railway car order recently placed with the Canadian Car and Foundry Co. will be made within the next two weeks. Some delay was caused through the inability of the car company to obtain steel for this business, but both the Nova Scotia Steel Co. and Steel Company of Canada are now making regular deliveries, and within the next month the company will be turning out fifty cars per day. The Fort William, Montreal and Amherst plants are all engaged on this order, the output of the Amherst plant having increased from two to ten stock cars per day during the past few weeks.

Oil-Burners Must Use Coal.—Increased demand for fuel oil in the war on the Atlantic, which makes the liquid much less plentiful than on the Pacific Coast, has resulted in a decision to remove oil burners from the Cunarder War Viceroy and convert the furnaces into coal burners. The ship is now in the north, and as soon as it returns to its home port the change will be effected. Conditions are now practically the reverse to what they were a few years ago, when many of the steamship lines were outfitting their coal-burning vessels with facilities for using oil as a power medium. In view of the war conditions, it is thought that all of the steamers building on the Pacific Coast that are intended for service on the Atlantic will be coal burners, while the wooden vessels in the Pacific will use oil.

Oil and Gas Development in N.B.—The oil and natural gas development in Westmoreland County, New Brunswick, is making satisfactory progress. During the past year several of the wells were deepened and increased flow obtained. The natural gas is sold under contract to a Moncton corporation, which acts as distributing agent. The total number of domestic consumers of the gas in Moncton and adjoining territory last year was 2,824. The gas is also used by the Canadian Government Railways for their gas engines and forges at the Moncton shops, and by the Plaster Works of the Albert Manufacturing Co., of Hillsboro. The value of the gas produced last year is estimated at $7,936.37. Arrangements have been about completed for the sale of all the company's crude oil to a manufacturing plant at New Glasgow, N.S.

Tungsten Production in N.B.—A very interesting development of wolframite or tungsten is in progress at Burnt Hill on the South West Miramichi, New Brunswick. This metal is extensively employed in the manufacture of high speed steel and armor plate. As the Imperial Government has commandeered for its own use all of the metal of this kind in the empire, the successful development of this provincial prospect possesses more than local interest. The company has erected a concentrating mill at the water's edge of the Miramichi River, for the treatment of the ore as it is taken from the mine. A shaft 65 feet deep has been opened up to follow the vein in two directions. The mine is equipped with steam hoisting apparatus, and air compressor for the drills. The vein of ore is about four feet in thickness and is nearly vertical.

Building Sternwheelers at Yarrows.—The steel sternwheelers which have been built for delivery in India by the Esquimalt branch of Yarrows, Ltd., have given such satisfaction that another contract for a vessel of similar type has been placed with the concern by another com-

pany. Yarrows, Ltd., is already working on a contract for four sternwheelers, two having been finished and put into service, while the other two are under construction. After being fully assembled at the Esquimalt yards and placed in readiness for the water, the vessels, which are of extremely light draught and practically flat-bottomed, are "knocked down" and the parts shipped to the Orient, where they are re-assembled and put in running order again. They are used almost entirely for river navigation. The latest contract is for a vessel 185 feet long, with a 37-foot beam.

Ottawa, Ont.—Assistant City Engineer Askwith has been given permission to call for tenders on the supply of an apparatus for thawing out city water pipes. The style of apparatus the engineer desires is gasoline-driven and mounted on sleighs. The estimated cost is $3,500.

Armagh, Que.—Gauvin & Beauchemin, civil engineers, Quebec, Que., are preparing plans and specifications for power development at Armagh, County Bellechasse, on River Fourche-du-Nord-Ouest, and will receive tenders for water turbines, dynamos, sluice-gates, penstock and wooden pipes, etc.

Winnipeg, Man.—Tenders will be received by the Commissioners of the Greater Winnipeg Water District up to Monday, Nov. 26, 1917, for the following:—Construction of tunnel, shafts and well at the Red River crossing; supply of cast iron gate valves, air valves and sluice gates, construction of gate house and intake at Waugh, Man. Specifications may be obtained on application at the office of the District, 501 Tribune Bldg., Winnipeg. R. D. Waugh, Chairman of Commissioners.

Winnipeg, Man.—Tenders will be received up to Monday, Dec. 3, 1917, by the Commissioners of the Greater Winnipeg Water District for the following: Construction of a pressure pipe line from Red River to McPhillips Street Reservoir; manufacture and supply of 48-inch pre-moulded reinforced concrete pressure pipe; supply of cast iron pipe and specials. Specifications may be obtained on application at the office of the District. 501 Tribune Bldg.. Winnipeg. R. D. Waugh, Chairman of Commissioners.

Port Arthur, Ont.—Tenders will be received until Monday, November 26. 1917, for the construction of a temporary pile protection breakwater at Port Arthur, District of Thunder Bay and Rainy River, Ont. Plans and forms of contract can be seen and specifications and forms of tender obtained at the Department of Public Works, Ottawa, and at the offices of the District Engineers, Equity Building, Toronto, Ont.; Sault Ste. Marie, Ont., and Port Arthur, Ont.

St. John, N.B.—J. Fred Belyea proposes erecting a sardine canning plant at West St. John, to cost $90.000.

Regina, Sask.—The Saskatchewan Co-operative Elevator Co. will rebuild the elevators at Maryfield and Raymore, which were destroyed by fire.

The function of lubricating oil is to give the greatest ease of motion to all parts of the engine, so that every possible atom of power may be transmitted to the machines. An oil that will do this will have effect on other divisions. Ease of operation would mean elimination of friction, no wear on the bearings, less oiling. Pure oil would be a decided labor-saving, cost-reducing, efficiency-promoting factor in the engine room. A great many Canadian manufacturers have pronounced our "Non-Corrosive Cylinder Oil" pure. We, who know its construction, pronounce it pure. Get in touch with us.

damaged by fire on Nov. 6, which was discovered in the stock or finishing-room. A large quantity of finished stock was destroyed by fire and water. The loss is covered by insurance.

Lindsay, Ont.—H. E. Hunt, of Chicago, Ill., has been here for the purpose, it is said, of looking over the town with a view to establishing a Canadian factory Kinleith Paper Co.'s mill was seriously for the manufacture of a special brand of leather for use in automobiles, upholstering, etc. A factory will also be established in the United States.

St. John, N.B.—The grain elevator being built by the Fegles-Bellowes Co. for the Canadian Government Railways, is approaching completion. The concrete substructure is practically complete, and the workmen are now employed on the steel super-structure, which will be 100 feet in height. The capacity of the first unit of this elevator will be 500,000 bushels. The re-building of No. 5 warehouse on the western side of the harbor is being proceeded with by Kane & Ring, contractors.

Lethbridge, Alta.—The City Council contemplate the installation of power plant equipment costing $63,000.

Bienville, Que.—The Town Council will call tenders for turbine pump for waterworks.

Ottawa, Ont.—The tender of the Otis-Fensom Elevator Co., $1,862, was the lowest received on the supply of an elevator for the city workshop on Chamberlain Avenue. The tenders were referred to the engineer.

Toronto, Ont.—The City Council has given the Toronto Board of Harbor Commissioners authority to sell industrial sites, covering 139 acres, on the northerly part of Ashbridge's Bay industrial area, east of Leslie Street. The sale of four acres in this section at $15,000 to the Imperial Oil Co. has been confirmed by the Council.

CATALOGUES

Brass Foundry Equipment.—Catalogue No. 128 illustrates and describes a line of equipment for brass foundries, such as furnaces, tumblers and tongs, etc. The catalogue is fully illustrated and includes tables of sizes.

Insulating Bricks for Boilers.—The Armstrong Cork & Insulation Co., Pittsburgh, Pa., have issued a folder, just off the press, bearing the title "Nonpareil Insulating Brick for Boiler Settings." The folder states what this type of brick is composed of, and also gives particulars of tests. Copies of this folder may be had free of charge on request.

The Whiting Converter is the title of a new catalogue No. 129 issued by the Whiting Foundry Equipment Co., Harvey, Ill. The catalogue deals with the construction and principal features of the Whiting side-blow steel converter, and also describes the process of making steel castings by this method. The catalogue is fully illustrated, showing a number of installations.

Adjustable Speed Motors.—Bulletin No. 41021, issued by the Canadian General Electric Co., Toronto, deals with the R.F. adjustable speed motors. The principal characteristics and other important features embodied in this line of motors are given in detail, accompanied by illustrations showing various types and details of parts. A table of dimensions covering the various sizes is also included.

BOOK REVIEWS

First Aid Instructions for Miners, a booklet, pocket size, issued by the Bureau of Mines, Department of the Interior, Washington, D.C. This handbook contains a report on standardization of advanced first aid instructions for miners, compiled by a committee of surgeons appointed to formulate in detail methods of giving first aid instruction to miners for the various classes of injury that were likely to take place in mines. The handbook contains much valuable information on this important subject, presented in a clear and concise manner. The handbook contains 163 pages, 65 illustrations and a complete index. Copies with paper covers may be obtained from the Superintendent of Documents, Government Printing Office, Washington, D.C., for 20c. An edition in stiff covers has been issued at 35c per copy.

Rural Planning and Development.—The latest report of the Commission of Conservation deals with the important subject of the planning and development of rural districts and small towns in Canada. It has been prepared by Thomas Adams, Town Planning Adviser of the Commission, who has made a close study of the problems of rural development in this country during the past three years, following twenty-five years experience in farming, land surveying and town planning in other countries. The report deals comprehensively with the social conditions and tendencies in rural areas and the prevailing systems of land settlement and development. It indicates the rural problems requiring solution in order to secure the proper development and economic use of land for purpose of efficiency, health, convenience, and amenity. The great injury which land development in Canada suffers, from speculation, neglect of public health, and want of expert business administration of land settlement, is considered. Incidentally, the problem of returned soldiers is dealt with, and the connection between land development and such questions as taxation, unemployment, and high cost of living is clearly shown. Having regard to the need for more attention being given to production in Canada, to the extent to which production is impaired by speculation in land, by neglect of public health, and by haphazard systems of development; to the importance of increasing the supply of human skill and energy and of capital derived from production instead of by borrowing, the problems dealt with in this report are of vital and current interest to the people of this country.

CANADA'S DEPARTMENTAL HOUSE FOR MECHANICAL GOODS

STANDARD SUPER-HOT SPECIAL SOFT RED CONDENSER

Rub-Steel Valves

"THE VALVE WITH A BACKBONE"

WHAT IS IT? The RUB-STEEL VALVE is a valve made by a combination of rubber and steel.

THE CONSTRUCTION The construction consists of a plate of high grade steel placed in the center of the valve with a specially tough and lasting rubber composition on each side and edge, attached securely and lastingly to the metal by the Elchemco process, which chemically unites the rubber and steel.

THE PURPOSE The steel plate gives such strength to the valve that the highest pressure cannot warp, twist or in any way get it out of shape, while the rubber surfaces afford the proper seating qualities. **"Better than Metal Because of the Rubber—Better than Rubber Because of the Metal."**

WHAT IT ACCOMPLISHES It gives the valve a rigidity of form. It keeps the surface of the valve in its normal true position and insures a better seating quality. It prevents the high pressure from forcing the valve through the grating. It prevents the rubber from breaking up and the pieces causing trouble. It holds the surface of the valve in shape, so that when one side becomes worn the valve can be reversed without dressing. It is thinner and therefore gives greater efficiency to the pump. It permits the use of a softer valve for hot water, thus securing a better seat on worn or uneven "grids." It ensures an even distribution of the pressure, preventing "dishing" and the consequent cutting of the valve.

WHY YOU WANT IT **Because** its ultimate cost is less than that of ordinary type valves. **Because** it will last longer than other valves. **Because** it saves time and annoyance of replacement. **Because** its construction at once appeals to you as practical and sensible.

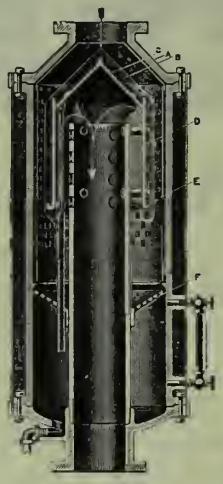
III IMPORTANT THINGS

TO CONSIDER ABOUT A SEPARATOR.



I. THE PLAN—Is it sensible, will it work, no matter how large the Separator or how well made?

II. THE SIZE—Is it big enough regardless of plan, will it hold a good dose of water?

III. THE CONSTRUCTION—Is it strong enough, are flanges heavy, how will it look by the side of a nicely finished engine? Send for catalog and note these points in

Belting is Machinery

Belting isn't an accessory to machinery—belting is machinery. Buy a belt just as you buy a machine. The right belt takes up all the power; carries all the power; delivers all the power.

For every drive there is one right belt. For example: Graton & Knight Spartan, an extra-durable leather belt, is standardized for difficult machine shop work, overload drives, or exposure to oil, fumes, or other adverse conditions. Graton & Knight Neptune, standardized for damp and wet places. Graton & Knight Heart, GraKnight, and GraKnight Dynamo, the standardized extra heavy, medium and light weight oak-tanned center stock belts respectively.

And so on, through the whole gamut of power transmission, there is a Graton & Knight Leather Belt that is standardized for each and every belting job.

Don't try to save money by cheapening your belting—the right way, the profitable way is to standardize it. A Graton & Knight Belt Expert will show you how to put the right belt to work in the right place. Let us send him to see you—there's no obligation.

Escaped from Germany

AN escaped prisoner tells the story of his fearful experiences in Germany in MACLEAN'S MAGAZINE for November; and gives a vivid picture of conditions in Germany as he saw them. He got out by way of Holland after appalling perils and hardships. In Holland, he was photographed, but so altered was he that his wife quite failed to recognize him in this photograph. Read this story of this Canadian soldier's escape. It is gripping stuff—a rare tale.

Canadian Finances After the War

WILL business in Canada collapse when peace comes? It may. What do the big men say? What do they know? What do you think? Are your opinions well informed? The subject is of the greatest possible importance, and you will get light and leading by reading the contribution of Col. John Bayne Maclean, who has taken the trouble to get the opinion of the biggest and most highly placed men in Canada to help him prepare his article.

Back from the Arctic

WILLIAM THOMPSON, representing the American Geographical Society, was this year in the Arctic Regions. He went to the delta of the Mackenzie River, and took many excellent pictures of the country and its Eskimo inhabitants. He makes the November MACLEAN'S the vehicle of many of his pictures and for an account of his journey. Read what this Arctic scientist has to tell us about a remote part of our land.

Slackers and Conscription

WHAT is your attitude towards the draft? You have positive opinions, of course. How do they square with Miss Laut's as they are expressed in her ringing article on Slackers in the November MACLEAN'S?

The Nation's Business

THIS is a new feature—a fearless, well-informed survey of national affairs. What we all want is an outspoken—but not vindictive—and clear-visioned presentation of factors and facts affecting our national, political and economic welfare.

Sketches of Trench Life

By Gunner McRitchie

MCRITCHIE was a cartoonist on a Western Canada daily before he went overseas. He has done a number of sketches of trench life "On the Spot," and these he has sent home, for publication in MACLEAN'S MAGAZINE. They're interesting and good.

The Late Sir Mortimer Clark

BEFORE he died, a few week ago, the late Sir Mortimer Clark, eminent jurist and an ex-Lieutenant-Governor of Ontario, wrote for MACLEAN'S an article on "Safeguarding Your Heirs." It has to do with the functions, service and safety of Trust Companies as executors of estates. This article by a man so distinguished, so cautious, so able, and so wise a counsellor, can be of first-rate value to every man perplexed with the problem of how his estate can be safely and prudently administered after he, the testator, has passed from this life.

A Complete Novelette

By Peter B. Kyne

HIS story in the November MACLEAN'S is a thunderingly good story of lumbermen and lumbering. Red blood is in this tale of business. R. M. Brinkerhoff illustrates it.

Short Story

By Ethel Watts Mumford

THE writer of this short story—the first of a delightful series by this author to appear in MACLEAN'S—is very well known among short story writers. Delicate fancy, wholesomeness, freshness and finished workmanship characterize all her work.

Short Story

By W. A. Fraser

A MIGHTILY well-written story of India—the kind that we all delight in; tense, bewildering, and lots of action. Fraser never wrote a better short story than this. Ben Ward illustrates it.

Hendryx and Oppenheim

SERIALISTS

"THE Gun Brand," by Hendryx, comes to an end in the November issue. Oppenheim's greatest story, "The Pawns Count," is continued. Oppenheim's story is the biggest single feature ever secured by MACLEAN'S.

MACLEAN'S MAGAZINE

for November At All News Dealers **15c.**

BEHIND this Diamond Trade-Mark on every Jenkins Bros.' Valve is the 53 years' reputation for Quality Products and trustworthy service.

Constant improvement to meet the varying conditions of valve practice and usage since 1864, has made possible the maintenance of the Jenkins Bros.' guarantee—

"If you will put a genuine JENKINS BROS.' VALVE on the worst place you can find, where you cannot keep other valves tight, and if it is not perfectly tight, or does not hold steam, oils, acids, water or other fluids longer than any other valve—**you may return it and your money will be refunded."**

Leading Engineers no longer buy valve service on manufacturers say-so. They insist on a definite record of accomplishments—facts. JENKINS BROS.' VALVES invite investigation on a fact basis.

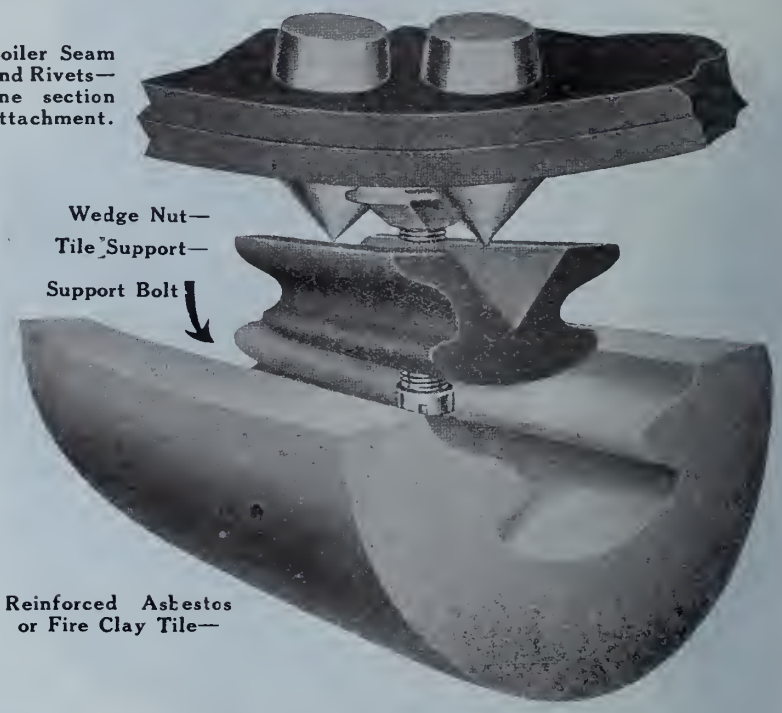
THIS IS IT



The illustration above shows one complete section of this National Protector. Five such sections make the National Boiler Girth Seam Protector.

Howard Smith Paper Mills, Beauharnois, Que. Dominion Copper Products Co., Montreal; Montreal Cotton Mills, Valleyfield, Que.; National Bridge Co., Ltd., Longue Point, Que.; Montreal Locomotive Works, Montreal, Que., and hundreds of other firms who realize the advantage and benefit derived by having this Protector.

EXPRESSIONS OF LEADING BOILER INSPECTORS AND ENGINEERS.

Prominent Government Inspector—It should be on every R. T. Boiler, new or old, as it fills a long-felt want.

Consulting Engineer—There is no doubt as to its merits, and will recommend it to be adopted on all boilers under my supervision.

Factory Superintendent—Our cost in boiler repairs has been enormous, not counting necessity of shutting down. This Protector we have been wanting for some time and will have it put on every boiler where it can be attached.

Now it is up to you. Is not Protection and Prevention better than Risk.

Canadian Association of Stationary Engineers

Incorporated May, 1887 — Incorporated at Ottawa, June, 1917

An organization having as its aims and objects:—

To promote the knowledge of its members in the art and science of Steam Engineering.

The dissemination of information beneficial to the members of the association in the discharge of their calling.

To further and protect the interests of competent engineers, and receive such as members of this organization.

To secure, through proper legislation, the greatest security in operation of steam plants.

To assist unemployed members to secure positions.

To maintain freedom of action between employer and employee.

The members of the Association subscribe to the above in the full belief that ability and knowledge of one's profession are necessary to insure the highest degree of success.

Labor Study Energy

These three essentials have been responsible for the success of the world's greatest men. They are no less essential for yours. We cannot all become great, but this fact does not lessen the necessity for the exercise of these essentials in our individual occupations. Cool, calm, calculating judgment characterizes the successful power house operator of to-day. The demands on the engineer of to-day are many, and the obstacles in his path are great. To assist in the overcoming of these and help the accomplishment of great works, material, moral and educational, is the desire of all our members.

The benefits accruing from association with members of his fraternity, the opportunity to benefit by their experience, and the inspiration to greater effort by reason of their success render membership in this association indispensable to all progressive engineers.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

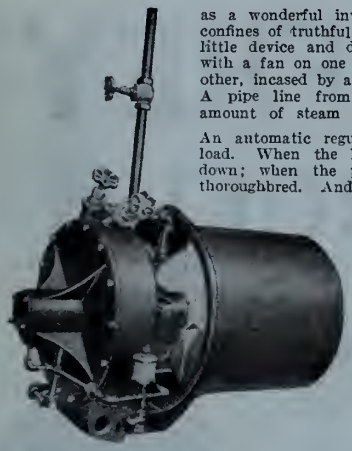
J. H. HALE, General Secretary, C.A.S.E.

230 Caroline Street — Hamilton, Ont.

"Doing Our Bit"

We believe we are "doing our bit" in demonstrating to manufacturers how they can effectively cut down the cost of steam production, better their combustion and increase the capacities of their boilers. In offering the

Coe Turbine Blower



as a wonderful invention, we are well within the confines of truthful advertising. It is such a simple little device and does such a big work! A shaft with a fan on one end and a steam turbine on the other, incased by a shell is about all there is to it. A pipe line from the leader supplies the small amount of steam required.

An automatic regulator adjusts the speed to the load. When the load is light, the blower slows down; when the peak comes it responds like a thoroughbred. And how it does drive the air into the fire! Clinker doesn't get a chance to form.

The gases of combustion which ordinarily pass up the chimney are held back by the draft controller, thoroughly mixed with the air and burned. Nothing gets away that is worth keeping.

Space limits prevent a complete description of the Coe Turbine Blower. Write for it and receive our special demonstration proposition. You should have it. We solicit your inquiry.

Floor Troubles Meet Their Waterloo At Waterloo, New York

The concrete floors of the Empire Gas & Electric Company have been made permanently non-dusting, non-crumbling and non-expensive!

R.I.W. REMEMBER IT'S WATERPROOF — REG. U.S. PAT. OFF.
CEMENT FILLER & CEMENT FLOOR PAINT — PATENTED AS TO PORTLAND CEMENT FEB. 27 1906

This is a combination cement floor treatment that doesn't fear water, oil, acids, alkalies, floor trucks, the vibrations of heavy machinery, or the scuffings of a thousand rough-shod feet.

It hardens the floor by filling its pores and rendering it impermeable to water, oils, acids, alkalies, etc.

It decorates the floor by laying a hard, pleasingly glossy coat in any of twelve standard shades, or special shades to suit.

It stops dusting—and the consequent damage to moving machinery by fine particles of floating concrete dust.

Write for our Booklet about it—No. 59.

MARSH and AMERICAN
Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction*. Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under auy unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring olled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

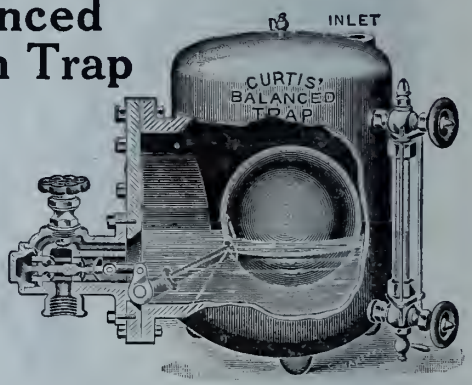
Balanced Steam Trap



This trap is often used as a waterline trap on large plants where there is need to balance any particular circulation to prevent snapping and cracking in pipes and radiators.

This Trap Has These Points of Difference and Superiority

1—A perfectly balanced valve.
2—An absolutely frictionless valve.
3—The valve can be removed without breaking a joint, starting a gasket, or taking out a bolt.
4—The valve being frictionless and balanced, the whole power of the float is available for opening and closing the valve.
5—Each trap will operate perfectly on pressure varying from one to 250 lbs.

The great merit of this trap, its simplicity, its dependability and serviceability make it well worth being better acquainted with. Send for special printed matter describing it and giving prices. Address the Manufacturers.

Globe and Angle Patterns

Playing the game *safe!*

Where boilers are connected in battery the danger incident to the blowing out of a tube, rupture of the shell, etc., increases in direct proportion to the number of boilers unless *each boiler is provided with a Lunkenheimer Non-return Safety Boiler Stop Valve.*

When thus equipped, a sudden reduction in pressure in any one of the boilers will cause the Lunkenheimer Non-return Safety Boiler Stop Valve attached to the boiler to instantly close, and isolate the disabled one from the others in the battery.

It thereby safeguards life and property and facilitates the safe and continued operation of the other boilers without loss of time.

It will also prevent steam being turned into a boiler that has been cut out for cleaning or repairs, as this valve cannot be opened by hand. And when placing a boiler in service it will not open until the boiler generates steam to the pressure in the steam main.

To play the game *safe,* specify "Lunkenheimer" and insist on their installation.

Our "Age of Safety" Booklet No. 525-DC will interest you. Write for a copy.

Lunkenheimer Steam Boiler Valves and Fittings are registered for use in Canada. Complete list of Registration Numbers will be sent on request.

BABBITT STEAM SPECIALTY COMPANY

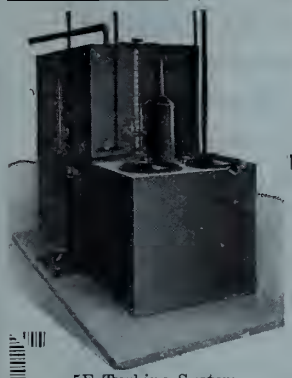
59 So. Water Street — NEW BEDFORD, MASS.

Manufactured in Canada, under Canadian patent by the Engineering Specialties Co., Ltd., 1080 King St. West, Toronto, Ont., Can.

ALBANY GREASE

is a most efficient, economical and dependable lubricant. It can be used, on account of its high lubricating qualities and its low melting point in any kind of grease cup and for every bearing in your plant. Use Albany Grease on your engines, pumps, compressors, motors, line shafting and special machines—always. We will gladly send you a quantity of Albany Grease to try and an Albany Cup. No charge of course. Write—now.

ALBANY LUBRICATING CO.
708-10 Washington Street, New York
ESTABLISHED 1868



5F Turbine System.

Suggestions *that* Lower Costs . .

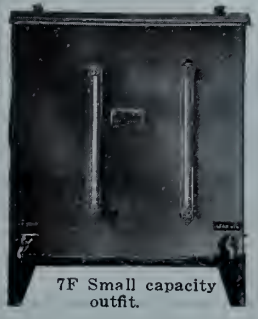
You cannot afford to overlook equipment that will reduce waste and operating expense, or increase production. Investigate the Bowser Oil Circulating and Filtering System, learn how it will prolong the life of machines, reduce coal consumption and repair bills by maintaining a steady flow of pure oil to every point of friction. Keeps oil pure and cool. No oil is lost.

BOWSER

Oil Circulating *and* Filtering Systems

Are built for any requirement, large or small. Their durability, simplicity and accuracy, also the ease of cleaning filter sections are "Reasons Why" Bowser Systems are in use in several of the largest plants in the country.

2F System.



7F Small capacity outfit.

Let us know your needs to-day.

Slip—or go through!

CASE 1—With a gripping surface of more than half its length, the tank is almost a part of the ground. It can't slip, for that would require more power than it does to move the load! Did you ever think of it that way?

CASE 2—Take the simple band brake, for instance: a strip of steel encircling a drum. When drawn down tight, all that outside surface is in contact, and the drum stops. Why? Because it takes more power to resist the brake than it does to stop the drum!

CASE 3—Consider the slack belt. The top side of the drive drops down on the two pulleys, increasing the arc of contact. It is harder for the belts and pulleys to slip than to carry the load, so they don't slip!

Here's a belt which has been running slack with CLING-SURFACE treatment for 12 years. Before CLING-SURFACE was used they were going to get a larger belt and bigger pulleys because this belt, run tight, slipped and would not pull the load. Instead, at a mere fraction of the cost, they treated it with CLING-SURFACE, prevented the slipping, and let it run slack. It now carries a 15% overload.

And that's exactly what the slack drive will mean for your belts—increased contact, more power delivered and slipping prevented.

All belts, and rope drives as well, on any centres, can be run easy or slack with CLING-SURFACE.

Send for a can for 60 days' trial. We will guarantee that you'll obtain these results BEFORE you pay for it. Isn't it worth the one-minute effort to you to have this increased power with absolutely trouble-proof drives? Then write to-day—tear out this ad and put it on the "to be answered" pile now.

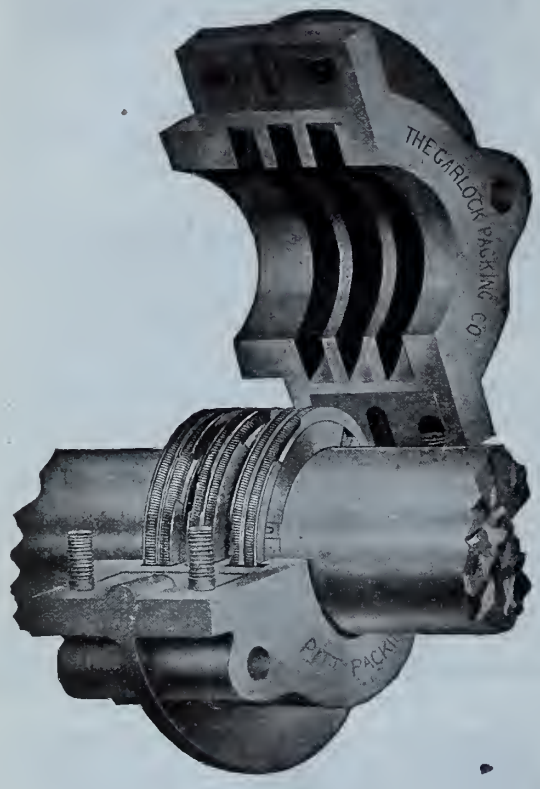
GARLOCK

Metal Packing



Our position in the Metal Packing field is based on the principle that "No one style of metal packing can be made to meet all conditions." Our experts study carefully the conditions surrounding each case to determine which type of packing is best suited to the conditions.

The accompanying illustration shows our Flexible Packing, with split case, which is the best all-around packing for stationary work, and when recommended by us to meet stated conditions it is guaranteed to give satisfactory service. This style is also made with solid or split case to fit inside of stuffing box, when packing space is sufficient to permit inside application of case and segments. Next to correct mechanical design the most important feature of metal packing is the material used in the bearing rings. Our materials are made from formulas which long experience has shown to give the best results. A special grade of cast iron is generally used for bearing segments, in order to secure minimum wear and friction, but under unusual conditions, or when considerable condensation enters stuffing box, bronze rings or segments of softer metal have to be used in the wearing parts. We can solve your metal packing problems, and we will give the usual Garlock guarantee of satisfactory service, if conditions are such as will admit of the successful use of any metal packing. Write for catalog describing our many styles of metal and fibrous packings.

Magnolia Metal Co.,
New York City.

Nov. 4, 1916.

Gentlemen,—I have been a user of Magnolia Metal for a number of years, using it in the kaolin and phosphate business, and have always found it to give better results than any other frictionless metal that I have used, and always specify it for repairs and new equipment.

Yours very truly,
G. C. Long, Chief Engineer.

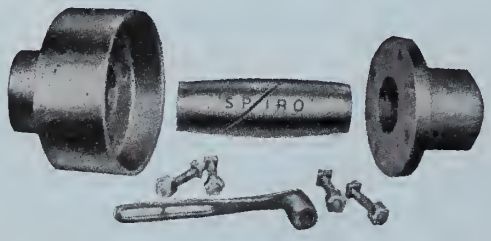
The Spiro Never Slips



The Spiro Compression Coupling is locked to the shaft by a graduated grip.
The pull of the bolts on the two halves of the coupling acts on the spiral slotted sleeve until it grips the full surface of the shaft with a never-slip hold.
Every bolt pulls, and at every pull the grip grows.
And last, but not least, the Spiro can be removed as quickly and easily as it can be applied.
The Bond Booklet describes our complete line of Power Transmission Devices.

The Joints of Morse Rocker-Joint Silent Chains

THE "ROCKER-JOINT" was devised over twenty years ago, long before the era of silent chains, as a scientific principle for eliminating frictional losses. It was immediately recognized throughout the mechanical world as *the one perfect joint.* The MORSE CHAIN CO. was the first to adapt this "ROCKER" principle to a chain joint, and the patent laws of every civilized country prevent its use on any other chain. Chain manufacturers everywhere have attempted to find a substitute for the "ROCKER" principle—some other principle which would also do away with the friction of the ordinary joint. But to this day the "ROCKER-JOINT" STANDS ALONE, the only chain joint which eliminates *destructive sliding friction.*

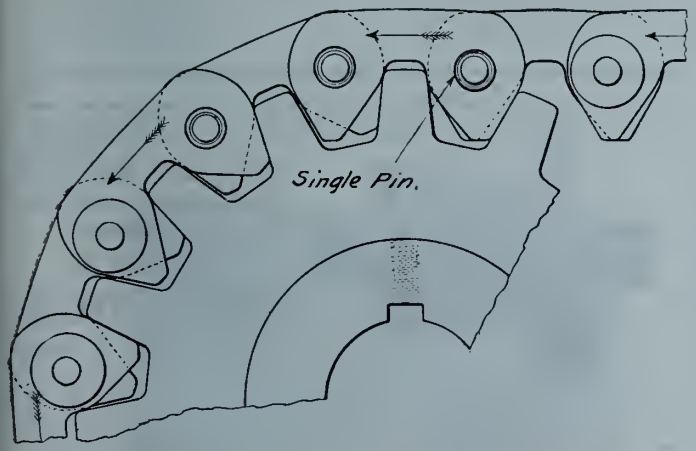

Fig. 1. The ordinary chain bending over the sprocket.

The ordinary silent chain joint is formed by a round hole at each end of each link, through which runs a round pin holding the rows of links together. This pin forms the axis about which the links twist in bending over the sprocket teeth. Obviously, as the load on the chain increases, the sliding friction on this single pin and on the holes of the link increases. A plentiful supply of lubricant and hardened bushings are essential to this joint and at best, wear and loss of power are certain.

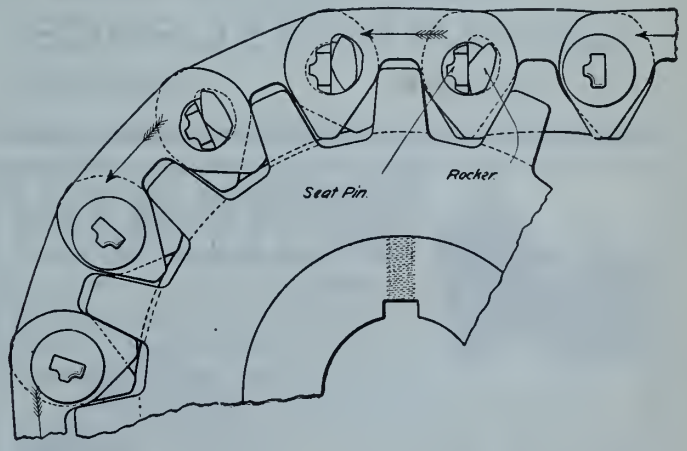

Fig. 2. The "Rocker-Joint" on the sprocket.

The "Rocker-Joint" is formed by two special, case-hardened steel pins, both of them seated in the holes of the links, the seat pin in the row of links to the right of the joint, and the Rocker pin in the row to the left. As the chain bends in circling around a sprocket, the curved side of the Rocker pin rolls or rocks upon the broad, flat side of the Seat pin. THIS IS THE ONLY MOVEMENT IN THE JOINT. There being no action between the hardened pins and the softer edges of the hole, bushings are unnecessary.

The "ROCKER-JOINT" depends upon its construction, not upon lubricant, for its life and efficiency.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways.
W. C. McGHIE, Chairman of Board.
W. A. RIDDELL, M. A. PH. D., Superintendent, Trades & Labour Branch.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914, With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

HON. F. G MACDIARMID, Minister of Public Works and Highways

W. A. RIDDELL, M.A. Ph.D., Supt. Trades & Labour Branch

Steam Trap

Points of Interest—

Self-contained strainer and sediment chambers.

Outside gauge glass furnishes evidence as to inside efficiency.

Three-inch water seal.

Counterbalanced seamless Lake Superior copper float.

Steam leaks stopped.

Can be adjusted to 60 lb. coil in the vacuum pans or a 160 lb. main to protect the engine.

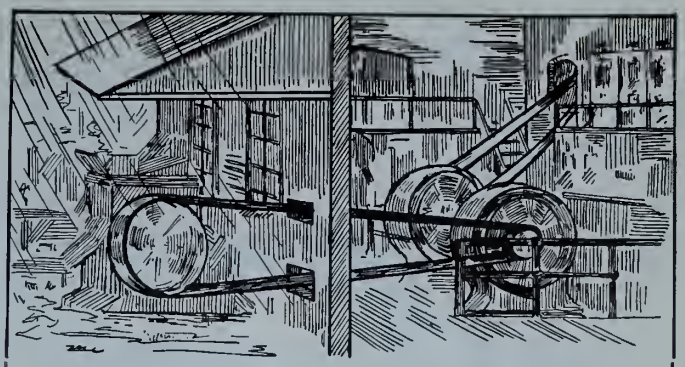
Used on any steam apparatus at pressures varying from 250 lbs. to gravity.

Used where there is any condensation in air lines.

Some points that explain why the Anderson Steam Trap is leading in the field of service. If you are troubled with condensation or any boiler room trouble, get in touch with us and secure our co-operation.

The V. D. Anderson Co.

1935 West 96th St.
Cleveland, Ohio



LANCO BALATA BELTING

From WET to DRY

Impregnated with Balata gum, Lanco Balata Belting is rendered proof against the penetration of water. This "Lanco Impregnation" of the most powerful, non-stretching fabric—long staple cotton duck tightly woven by our special process—gives you a belting that will serve longest under all but one atmospheric condition. The one exception is heat.

In service, Lanco Balata is as nearly stretchless as a good belt can be made. Use it wherever conditions constantly change from wet to dry.

Write to-day for our Belting Book.

Morehead
Back to Boiler
SYSTEM

60,000,000 Tons of Coal Thrown Away Yearly

Over 600,000,000 tons of coal are mined yearly in the United States and Canada. Ten per cent. of that enormous production is carelessly, needlessly wasted. Over Sixty Millions of Dollars are spent each year in producing—nothing, and yet, a mere fraction of that great loss, if properly applied, would save those wasted millions for years to come.

You are contributing to this national waste—but you can stop it.

Steam, after its expansive energy is exhausted, is not through with its job. There are heat units left—live, tangible heat units which were purchased by coal at the boiler's mouth.

What Are You Doing With These Heat Units?

This condensation, in other words.

With the Morehead System installed on your steam lines the condensation is automatically returned to the boiler—without pumps—and at any temperature. It is the last link from boiler back to boiler—the unused energy is not wasted.

If you would save this ten per cent. and have a clear steam system which drains automatically, write to-day for particulars.

The Vigilant

Feed Water Regulator is a perfected device that constantly

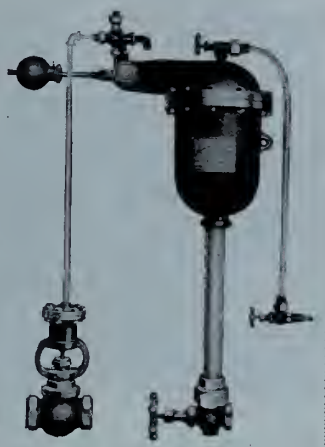
Keeps Water Level Within ¼ inch of Middle Gauge

Other devices may almost equal the Vigilant for a time. But with them you will learn all too soon that floats become water-logged, leaky or collapse in spite of guarantees to the contrary.

The Vigilant has but few parts and **no floats.** It gives no trouble. Throughout its long life it will provide absolute prevention from dangers of high or low water.

It will also reduce your coal bill from 3 to 17 per cent.

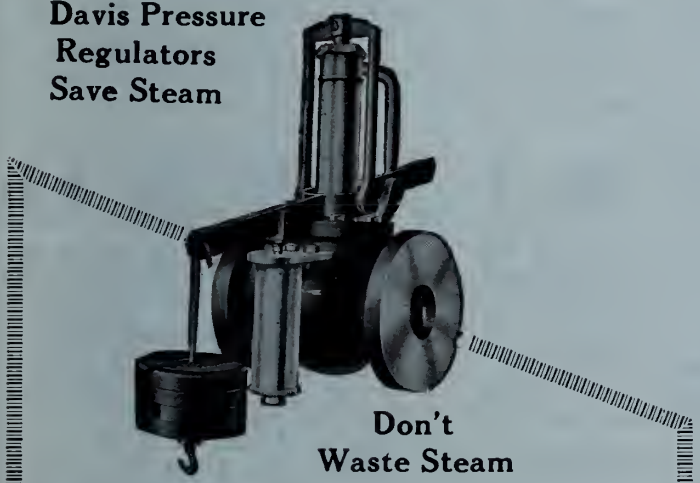
Write for Engineers' Data Cards.



The Chaplin-Fulton Manufacturing Co.

28 Penn Ave., Pittsburgh, Pa.

Davis Pressure Regulators Save Steam



Don't Waste Steam

You carry high boiler pressure for emergencies and peak loads, but are you sure this reserve is not slipping away? You know only too well the cost of coal —conserve it by keeping your steam pressure under full control with

DAVIS PRESSURE REGULATORS

Put these automatic valves to work wherever you can use less than boiler pressure. The cost is trifling and the saving big. Forty years on the market is enough to prove they are built right. Send for catalog. It will show you a way to cut costs.

G. M. DAVIS REGULATOR CO.
434 Milwaukee Avenue

LIGHT IS AN ASSET

The benefits of sunlight are thrust upon you, but you yourself must acquire the advantages of proper artificial lighting.

In thousands of power stations, sub-stations, factories, mills and offices, the real money-saving value of efficient artificial lighting is already appreciated and good light is considered an asset and production increaser.

In daytime skilled labor and high priced assistants perform their duties with accuracy and precision, but are you handicapping them during the dark hours and night shift by giving them insufficient artificial light?

Protect them against accidents and error risks and make their working vicinity bright and cheerful by using

LACO NITRO LAMP "THE LIGHT THAT GIVES MORE LIGHT"

This lamp is gaining daily in popularity because of its many superior merits over other type lamps.

Low in operating cost and high in efficient service. Uses less current and gives a clearer, brighter light than heretofore possible. Scientifically constructed with tungsten filament substantially suspended in nitrogen gas-filled bulb, thus securing long utility under severe usage.

Every Electrical Man Wants These Books and we ship them for your inspection FREE

Flexible Covers — Handy Pocket-Size Volumes

10 Numbers — 3500 Pages — 4700 Pictures

$1 A Volume
$1 A Month

Just what you need to know to succeed in ELECTRICITY

EVERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its branches.

You run into some new electrical problem almost every day. The information you need to help you in your everyday work is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain everyday language—no wasted words—only what you need to know—chock full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of the day's electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

What Electrical Men Say

Helped Him Make Good.

"It is only right for me to recommend highly the Hawkins Guides, for they have been of the greatest assistance to me in placing me in my present position as Superintendent of Construction Department of one of Ohio's largest Electrical Companies. I would like to see every man have a set of Hawkins Guides."

Geo. Knecht, Columbus, Ohio.

In the Naval Electrical Dept.

"The Hawkins Guides are great help to me in the Naval Electrical Department, which they cover very thoroughly." C. J. Cornell, U.S. Receiving Ship, Brooklyn, N.Y.

Superintendent

"I am now superintendent of the Dunnville Hydro-Electric Systems, and Hawkins Guides were a great help to me in holding down a responsible position."

W. E. Swartz, Dunnville, Ontario.

Wireless Operators

"I have worked wireless for ten years—but I wish I had these books years ago, as they have saved me a great deal of trouble." H. Marshall. Steamer M. & B. No. 2, Walkerville, Ont.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handsomely bound in flexible black covers.

You can carry each volume with you until you have mastered its contents. 3,500 pages of actual information and 4,700 illustrations. Once you see these books and put them into actual use you will never again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over—ask them all the questions you can think of—use them in your work—study them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes entirely FREE.

This is a sign of our confidence in the guides. Pure gold does not object to being tested. Keep them for seven days and if you do not decide that you can't get along without them, return them to us and owe us NOTHING.

When you decide to keep them you only have to pay $1.00 down and remit the balance of $9.00 on the easy payment of $1.00 a month till paid for.

Use this coupon to get the books. It will pay you many times over.

THEO. AUDEL & CO.
72 Fifth Avenue New York, N.Y.

READ THIS PARTIAL LIST OF CONTENTS.

No. 1 Contains 348 pages. 388 illustrations. Electrical signs and symbols—static current electricity—primary cells—conductors and insulators—resistance and conductivity—magnetism—induction coils—dynamo principles—classes of dynamos—armatures—windings—commutation—brushes, etc.

No. 2 Contains 348 pages, 394 illustrations. Motor principles—armature reaction—motor starting—calculations—brake horsepower—selection and installation of dynamo and motors—galvanometers—standard cells—current measurement—resistance measurement—voltmeters — wattmeters — watt hour meters—operation of dynamos—operation of motors, etc.

No. 3 Contains 300 pages 423 illustrations. Distribution systems—wire and wire calculations—inside, outside and underground wiring—sign flashers—lightning protection—rectifiers—storage battery systems, etc.

No. 4 Contains 270 pages, 379 illustrations. Alternating current principles—alternating current diagrams—the power factor—alternator principles—alternator construction—windings, etc.

No. 5 Contains 320 pages, 614 illustrations. A. C. Motors —synchronous and induction motor principles—A. C. commutator motors—induction motors, transformers; losses, construction, connections, tests—converters—rectifiers, etc.

No. 6 Contains 298 pages, 472 illustrations. Alternating current systems—switching devices—circuit breakers—relays—lightning protector apparatus—regulating devices—synchronous condensers—indicating devices—meters—power factor indicators—wave form measurement—switch boards, etc.

No. 7 Contains 316 pages, 379 illustrations. Alternating current, wiring power stations—turbines: management, selection, location, erection, testing, running, care and repair—telephones, etc.

No. 8 Contains 332 pages, 436 illustrations. Telegraph—simultaneous telegraphy and telephony—wireless—electric bells—electric lighting—photometry, etc.

No. 9 Contains 322 pages, 627 illustrations. Electric railways—electric locomotives—car lighting—trolley car operation — miscellaneous applications — motion pictures—gas engine ignition—automobile self-starters and lighting systems, electric vehicles, etc.

No. 10 Contains 513 pages, 599 illustrations. Elevators—cranes — pumps — air compressors—electric heating—electric welding—soldering and brazing—industrial electrolysis—electro plating—electro-therapeutic—X-rays, etc.

Also a complete 126-page ready reference index of the complete library. This index has been planned to render easily accessible all the vast information contained in the 10 electrical guides. There are over 13,500 cross references. You find what you want to know instantly.

THEO. AUDEL & CO.
72 Fifth Avenue
New York, N. Y.

Please submit me for examination Hawkins Electrical Guides (price $1 each). Ship at once, prepaid, the 10 numbers. If satisfactory I agree to send you $1 within seven days and to further mail you $1 each month until paid.

MILL SUPPLY DEPARTMENT **BEVERIDGE PAPER COMPANY, LIMITED**
17-19 ST. THERESE STREET, MONTREAL

MANUFACTURERS:—Now is the time for your Boiler Repairs—you can SAVE money and get UTMOST SATISFACTION by using our Boiler Specialties. NO SKILLED LABOR REQUIRED. Equally good for large or small repairs.

PROTECTO—Boiler Preservative—the king of boiler compounds, removes scale, prevents foaming and priming and absolutely guarantees pure steam.

PROTECTOCOAT—Elastic Paint for coating boiler brickwork—fills up all cracks, keeps out all cold air. The saving in fuel will more than repay cost.

PLIBRICO—A one-piece Plastic Jointless Furnace Lining for repairs, arches, bridge walls, etc.; does not break, crack or shell off like ordinary firebrick; forms a solid block. No skilled labor required to apply.

PLIBRICO BOND—High Temperature Cement—made in three grades. Does not burn out like ordinary fireclay. Guaranteed to stand 3100° F.

ENQUIRIES SOLICITED—FULL PARTICULARS ON APPLICATION.

Local Representatives:—J. M. Allen, 65 Bloor St. W., Toronto, W. Reid, 27 Celebration St., St. John, N.B., P. H. Cowan & Co., St. Johns, Nfld.

WATER SOFTENING OR FILTRATION

WM. B. SCAIFE & SONS CO. PITTSBURGH, PA.

Mention This Paper When Writing Advertisers

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CATALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compressors, etc.**

MACGOVERN & COMPANY, Inc.

114 Liberty St., New York City

Paid For Itself in Thirty Days

The chances are that if a device does not prove its worth in thirty days there is little chance that it ever will. But one of this

"Detroit" Systems for Handling Condensation

have records of paying for themselves in thirty days.

Not only will a "Detroit" System pay for itself in a short time, but will continue to save hundreds of dollars a year right in your boiler room by saving fuel.

In your boiler room, as in many others, there is perhaps no adequate provision made to return the condensation.

Better let us send you "Watch Your Condensation."

MADE IN CANADA

TRADE PENBERTHY MARK

REGRINDING BRASS VALVES

Are especially adapted for

The Shipbuilding Trade

Approved and Registered for 200 lbs. Steam Pressure.

For Marine Engineering

The Penberthy Regrinding Valve is specially suited. Made with the metal-to-metal seat, ground to a tight fit, which forms an ideal seat to resist the high velocity of steam. Heavy union bonnet ring secures bonnet to body, making a non-corrosive and steam tight connection. This bonnet construction appeals very strongly to the high grade Engineer. The finest quality of metal is used in making Penberthy Valves and it is liberally distributed throughout to insure strength and rigidity. Long, graceful sweep of body permits easy flow of liquids or steam, thereby reducing friction to a minimum.

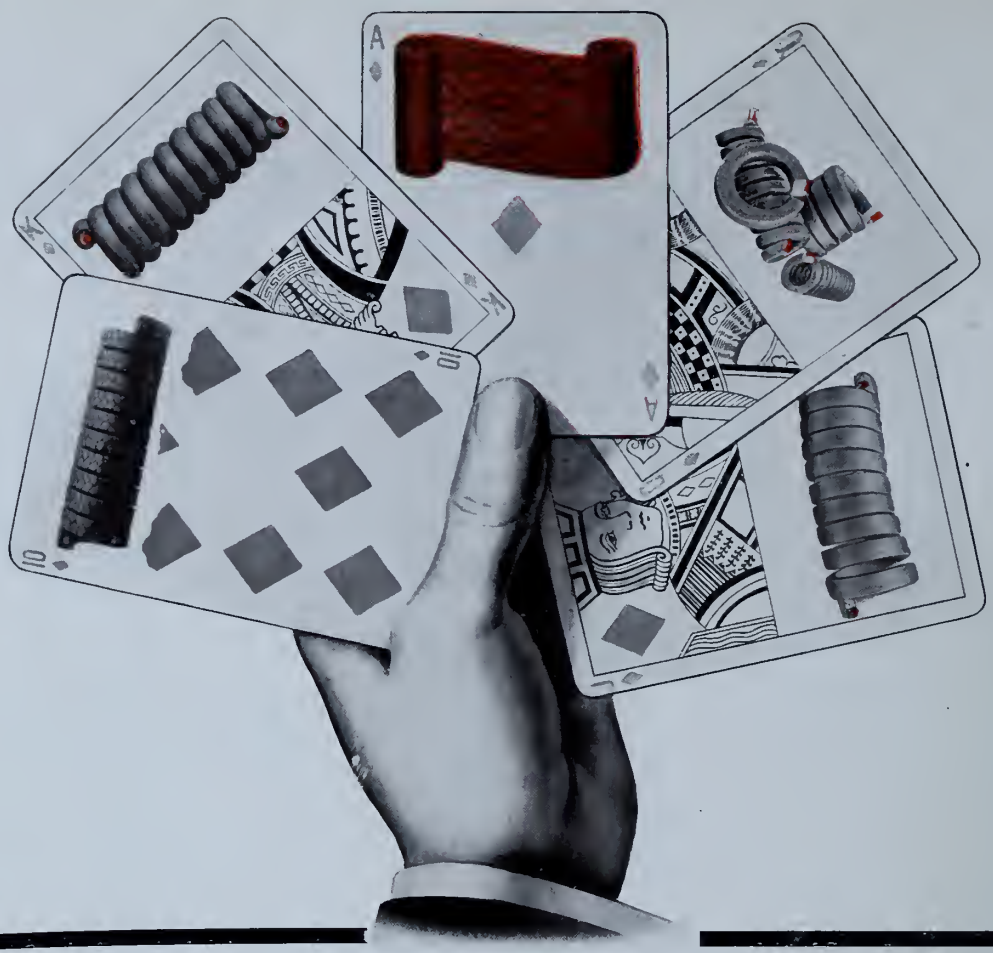
All valves fitted with packing glands and followers.

"PENBERTHY VALVES ARE JUST AS HIGH GRADE AS PENBERTHY INJECTORS."

Write for Free Valve Catalog.

Penberthy Injector Company, Limited, Windsor, Ontario

HIGH-GRADE VALVE MANUFACTURERS



A ROYAL FLUSH

That Calls the Bluff on Imitations

Every Peerless Packing is built up to a standard, not down to a price. They give service.

In these times when power plants are being forced to their limit it is policy to use the best packing you can buy, it means saving of power and time.

For economy's sake use Peerless Packings.

HOYT METALS

FOR well toward half a century Hoyt Babbitt Metals have fought friction by prevention. To-day—excepting enemy countries—they are giving super-service all over the world. Would our annual sales total over $5,000,000 if Frost King and other Hoyt Babbitts were not far and away superior?

Try Frost King—our general purpose Babbitt. We've put 40 years' Babbitt-making experience into compounding it.

Try Nickel Genuine—probably as perfect as an alloy can be made for use in gas and gasoline engines, all classes of marine engines and automobile engines.

Frost King and our specific purpose Babbitts are described in the Hoyt catalog. Also how these super-service Babbitts will lighten the Babbitt expense in your plant is told. Write for a copy.

HOYT METAL CO., Toronto

NEW YORK, N.Y. LONDON, ENG. ST. LOUIS, MO.

Fighting Friction

You Can't Eat a Boiler

and in appearance all boilers are much the same

SO what is a man to do? Provided he realizes that some boiler-building methods are good, that some are bad—and he doesn't know which is which—what is he to do?

Should he read what Boiler Builders have to say about their principles of design, their methods of construction, and their facilities for the work?

Should he see a Jenckes' Boiler under load and have a talk with the plant owner, the engineer and the fireman?

Should he quietly run down to the Jenckes' Works at St. Catharines, Ontario, and see for himself whether all he's been told about Jenckes' uncommon Boiler-Building facilities is correct?

Are these the things he should do? Well, if he takes half the care that these things suggest, he will select the best boiler made; and that is to say, our shipping department will load it.

Write for Jenckes' catalog of Horizontal Tubular, Vertical Tubular, Locomotive Types, and Heating Boilers.

JENCKES BOILERS

Get in Touch with Users of BOICO

Users include a large number of the biggest plants in Canada. We will be pleased to send you their names.

Boico does not contain any caustics or metallic substances. It will not injure packings, valves or any metals. It will not carry over in the steam, foam or prime.

It will keep your boiler free from scale and cut the cost of fuel, oil and packing. Write for *free* sample package.

Removes Boiler Scale and Prevents further Formation.

Anti-Clinker Shell Bar Grates

mean much more heat from much less coal. Half of their total surface is air space. It is this abundant air supply that commands perfect combustion—and perfect combustion adds 25% more heat to the fuel gases and prevents clinker formation. Say you want all the facts.

Daniel's P. P. P. and Ebonite Packings for all Pressures. Only packing backed with scientific proof that it reduces friction. Long tests by Mechanical Engineers proved that P. P. P. saved 75% or more friction losses. Automatically regulates bearings on rod to requirements.

Tip-It Patent Welding Process. Scarcity and high price of high-speed steel compels rigid economy in its use. TIP-IT welding makes it possible to obtain tools with carbon shank permanently united to cutting tip of high-speed steel.

Copper Asbestos Boiler Gaskets—most successful boiler gasket made. They never blow out and never stick. Made of corrugated copper, with pure asbestos, cord filled corrugations. Use them and end all leaks in pipe lines.

up! goes COAL

and as coal prices soar, mighty lively grows the demand for

The Jones Underfeed Automatic Stoker

Now supposing we installed a Jones Underfeed Automatic Stoker for *you* under your boilers and it sliced one-quarter off your coal bill;

Wouldn't that offset materially the high coal prices?

The Jones Underfeed Automatic Stoker will do more than greatly reduce consumption of coal in your boiler room.

It will give you more steam from less coal—and cheaper coal.

It will save the cost of coal-shoveling labor.

It will make your smoke stack smokeless.

It will pay for itself over and over, whether your boiler plant is large or small.

Write for our booklet illustrating Canadian installations and read what Canadian manufacturers say about the saving and service of the Jones Underfeed Automatic Stoker.

You Use It So Much—— Better Be Sure It's Good!

STEAM Hose is one of your important details. Year in and year out, it plays its part in the daily task of every engineer.

Because you use it so much, because it is an important part of engine room equipment—be sure it's good!

Steam and rubber are natural foes—as every man who handled hose has learned. Goodyear Steam Hose has been built with this knowledge. The inner rubber tube has been made as steam-resistant as Goodyear specialized skill and science can achieve.

As far as we believe is possible, the tendency for rubber to harden and crack under the action of steam has been overcome in Goodyear Steam Hose.

So, too, with the rubber cover—Goodyear laboratories have striven to produce a steam hose whose outer cover would adhere firmly and never blister or crack.

The plies are of durable fabric. They are welded together with a grade of rubber that remains elastic and active.

In short, in Goodyear you can get a steam hose that resists the action of steam—does not harden—stays flexible—lasts longer.

It offers you in the highest degree the trouble-saving qualities you seek—safety and economy.

Next time you take up with the "boss" a steam hose purchase, specify Goodyear. Tell him of the hose problems that Goodyear has solved for others. Suggest that he get in touch with the nearest Goodyear office and seek its expert advice on hose problems.

SERVICE STOCKS IN SMALLER CITIES

JOHNS-MANVILLE SERVICE COVERS THE CONTINENT

JOHNS-MANVILLE

Behind the Power that Turns the Wheels of Your Life

YOUR food, your clothing, your equipment for life's work, come from the collective efforts of thousands of manufacturing plants, which in the struggle to meet your demands, compete in quality, in price and in service.

To do this, these manufacturers must operate their establishments at highest efficiency—must protect their plants against countless costly leaks such as waste heat, friction, wear and tear, and breakdowns.

Many American manufacturers rely on Johns-Manville maintenance materials to check these losses. For example, they improve the efficiency of pumps and engines by packing them with Johns-Manville Sea Rings, the packing that reduces friction to a minimum. The brick arches over the blazing boiler fires are protected from the flame's white heat by Johns-Manville Refractory Cements. Again, the valuable heat transferred through pipes, ducts and flues is conserved by Insulations made from Johns-Manville Asbestos and Magnesia. And in hundreds of other instances, Johns-Manville materials are employed to reach you with a better product at the lowest cost.

So that of all the ways—some direct, some devious—by which Johns-Manville serves the public, none is more important than this function of maintenance, this power economy at the very heart-center of industry.

2,400,000 Board Feet of Nonpareil Corkboard Insulation Used in this New Building

This new building of the Chicago Cold Storage Warehouse Company, Chicago, Ill., is one of the most modern cold storage plants in the country. The interior structure of concrete and steel carries the load of the building and its contents, making it possible to enclose the entire building with a continuous envelope of Nonpareil Corkboard Insulation, and thus secure maximum protection against in-leakage of heat.

It is a significant fact that Nonpareil Corkboard is being used in most of the up-to-date plants, large and small. Its low heat conductivity, resistance to moisture, ease of erection and remarkable durability, make it the cheapest insulation in the long run that can be purchased.

The supporting structure of the building before the Nonpareil Corkboard was installed

Why not write for literature and sample?

Armstrong Cork & Insulation Company, 504 McGill Bldg., Montreal, Que.

Also makers of Nonpareil Cork Covering for cold pipes; Nonpareil High Pressure Covering for steam lines; Nonpareil Insulating Brick for boiler settings; Circle A Cork Brick for cold storage room floors; and Linotile for floors in offices, residences, etc.

Mechanical Refrigeration

is essential to success in many lines of manufacture, and YORK Products have played an important part in the development and expansion of these lines over the entire field.

We not only design and make a Refrigerating Plant suited to the needs of our customers, but all the details are handled by our own organization, which assures the best service possible.

YORK Refrigerating Machinery is the result of years of careful research, exhaustive tests, and the labor of experienced Engineers and competent Workmen; and for the Manufacturer who depends on the quality of his product for the continued success of his business, it is the logical equipment to buy.

Write us for information and prices.

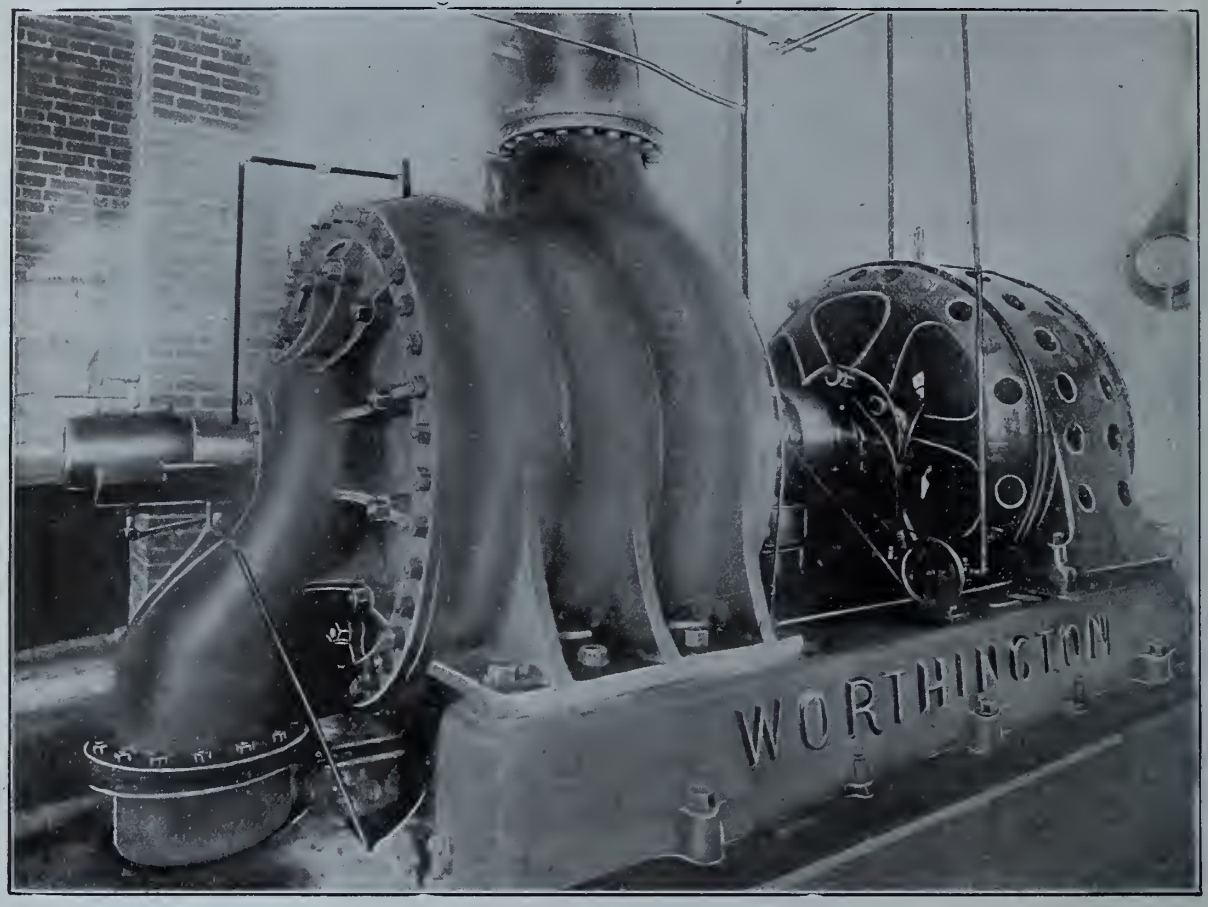
THE JOHN McDOUGALL CALEDONIAN IRON WORKS CO., Limited

Manufacturers of Boilers, Castings, Condensers, Elevators, Engines, Filters, Forgings, Hydraulic Machinery, Pumps — centrifugal and reciprocating, Steam Turbines, Tanks, Water Wheels, Water Works Plants

Works: Seigneurs and William Streets, MONTREAL



5,000,000 gallons daily—Montreal Water Works—Driven by 400 H.P. Induction Motor.

Our Engineers have spent many years developing Centrifugal Pumps and we are now able to offer you perfected designs in any size pump from inch and a half and up for any service you may desire, and to be driven either with motor, engine or belt.

Write us for Engineering information, or prices, any time.

Sole Canadian Agents for H. R. Worthington Co.

Keeping in Stock at Montreal a large assortment of their Boiler, Feed and General Service Pumps

Quarter Century of Progress.

The Canadian General Electric Co., Limited, was organized in September, 1892—just a quarter of a century ago.

It had its origin in a syndicate of ten citizens of Toronto formed five years previously with a capital of $10,000 to inquire into the feasibility of establishing, in Toronto, electric light and power by means of underground wires.

The Company has now a paid-up capital of $10,000,000.00, a surplus of over $4,000,000.00, and assets over $25,000,000.00.

It owns 10 manufacturing establishments shown above, a large Head Office and 7 Branch Office buildings, and has 5,000 to 6,000 employees.

The Canadian General Electric Co., Limited, manufactures Electrical Apparatus and Supplies for Railway, Light and Power purposes.

The Canadian Allis-Chalmers, Limited, a subsidiary company, manufactures Locomotives, Structural Steel, Cast-Iron Pipe and Power Plant Equipment, Mining, Crushing, Hydraulic and Milling Machinery.

By reason of its numerous factories and great manufacturing facilities, the company was able to take an early and leading part in the manufacture of Munitions of War, and recently obtained from the British Government an order for 4 Steel Steamships of 3,500 tons each.

This, briefly, is the record of a Quarter Century of Progress.

Plant, Equipment, and Product, The Goodyear Tire & Rubber Co of Canada.

The rise of rubber in industrial importance from a laboratory curiosity to one of the most indispensable substances of civilization, in peace or war, forms one of the romances of the nineteeth century. The extent to which rubber enters into the needs of mankind's daily existence are numerous beyond belief, and the immensity of the plant described in this article, devoted as it is to one special product, will serve to emphasize the importance of rubber.

THE factory which the Goodyear Tire & Rubber Co. of Canada, Ltd., have recently built at New Toronto, Ont., is symbolical of the remarkable success which has attended the automobile tire manufacturing business in the Dominion, and, judging from the plans which this concern has made for future enlargement, there is every expectation of even greater expansion in this industry. The Goodyear Co., as is perhaps well known, supplied until now the Canadian trade from their factory at Bowmanville, Ont. The need for greatly increased manufacturing facilities to meet the demand for their product ultimately became urgent, and New Toronto was selected as the best location for the new tire plant. The Bowmanville factory, however, is still in operation, and is devoted exclusively to the production of mechanical rubber goods. The removal of the tire plant to the new factory will permit of a greatly increased output of mechanical rubber goods at Bowmanville, while the production of tires at the New Toronto factory will, of course, be considerably greater than at the old plant.

Experience Plus System

Advantage has been taken of many years' experience in the tire business to plan the layout of machinery and equipment at the new factory, and in this respect it may be said that nothing has been omitted whereby the rapid and efficient production of tires is made possible. The various processes, from the mixing of the raw materials to the finished product, follow one another in regular sequence, with no waste effort or back trucking. Each operation or process has also been carefully planned to produce a perfect tire without any undue expenditure of either time or energy. The resultant efficiency enables producing costs to be kept within prescribed limits.

An elaborate cost system is employed, which enables the staff to keep track of all charges and eliminate unnecessary expenditure of time or material. An experimental department is maintained to try out new ideas either in the mixing of raw materials or in manufacturing processes. In connection with this department is a chemical and physical testing laboratory. The statistical department collects and prepares all kinds of data relative to the operations in the factory, while there is also an efficiency department. Needless to say, all the departments work together with the common aim of maintaining a high standard of over-all efficiency.

Social Features

A suggestion system is in force, many valuable ideas having been submitted by its means and adopted. Boxes with paper and pencil are located at various points to receive suggestions, and any practicable ideas are rewarded in a substantial manner, according to their value to the firm. This system has the advantage of making the employees interested in their work, as well as being beneficial to the company. A welfare department has been organized to adjust complaints and generally look after the health and comfort of the employees. In this connection an athletic field will be laid out and sports of all kinds instituted. This feature will not be inaugurated until the spring, when the weather will permit of laying out the grounds. On the top floor is a cafeteria, where four meals a day are served at cost price. This is a great convenience on account of the entire absence of restaurants in New Toronto.

The company have a property covering about 26 acres, with a frontage facing south on the Toronto-Hamilton Highway. The factory stands some way back from the road, thus leaving sufficient space for future extensions. A spur from the Grand Trunk Railway System enters the property at the back or north side, where the power house is located. The factory comprises one large main building, a power house, cement department and spreading room. The last three mentioned are separate buildings, and are at the back of the main structure. It is the intention of the company to lay out the grounds surrounding the factory in an attractive manner when the weather becomes more favorable for turfing and planting trees. The surroundings will be made as congenial as possible for the employees. The space in front of the main factory building is sufficiently large to allow of two more units being constructed, provision having been made for extensions when the present factory was planned. The same idea was kept in view when the power house was designed, extensions being possible without interfering in any way with the present layout.

Building Details

The main building is 460 feet long by 100 feet wide, and is laid out in 20 feet bays each way. The building comprises four storeys and basement, and is approximately 70 feet high from the ground level. The basement is 12 feet high, and the first floor 22 feet high. The second and third floors are both 15 feet high, while the top floor is 12 feet high to the lower chord of the roof truss, plus 5 feet for the latter. The general construction material of the building is steel and brick, all internal columns through-

out being encased in concrete. In the construction of the main building 2,200 tons of steel were used and approximately 2,225,000 brick. The brick work is of high quality in spite of the fact that the greater part of it was laid during the winter, the successful carrying on of the work being made possible by a liberal use of salamanders. The ground was broken in July, 1916, the erection of the steel work started in November, and the first brick laid on January 3, 1917. Manufacturing operations were commenced in September of this year.

Fenestra steel sash is used exclusively. There are approximately 45,000 sq. feet of sash in the main building, the sections being about 17 feet wide, and ranging from 8 ft. to 15 ft. high. Each sash is equipped with from one to four ventilators. The monitor in the roof, which extends the full length of the building, is made up of three rows of glass on each slope, two of these rows on each side being equipped with opening mechanisms operated by hand from the floor. With so much space devoted to windows, the factory is exceptionally bright and well ventilated. This feature strikes the visitor immediately upon entering, and is a valuable one in that it means healthy conditions for the employees, and consequently more efficient work.

The basement extends under the entire building except for 100 feet at the west end. The basement floor is made up of 8-inch concrete, on which is laid two ply of waterproofing material. On this again is laid 1½ inches of mastic ashphalt. Under the floor is a complete system of tile drainage leading to sewers which are laid in the centre of the building throughout its entire length. There are three lines of sewers for drainage, rainwater, and water from the factory respectively. Downspouts from the roof are placed 40 feet apart inside the building, and are carried to one of the above-mentioned sewers. The first floor is made up of 2 by 4's, laminated on steel and finished with maple flooring for a length of 320 feet.

Another section of the floor, comprising 60 feet, is concrete on steel, with mastic finish laid on waterproofing. The remaining 80 feet is composed of wood blocks laid on concrete. The second floor is made up of 2 by 4's, laminated on steel, with maple finish, except for 80 feet, which consists of wood blocks on concrete. The third floor is composed of laminated 2 by 4's laid on the steel, with maple finish, except for a length of 80 feet at the west end, which is of concrete with cement finish and hardened. The fourth floor is of the same construction as the third. The roof is constructed of 1⅞ by 6 in. boards laid on steel purlins and covered with 4-ply felt. The pitch was poured and not mopped, while the felt is covered with slag instead of gravel.

FIG. 1. COMPOUNDING DEPARTMENT WHERE RUBBER AND THE VARIOUS INGREDIENTS ARE WEIGHED AND PLACED IN BOXES.

Elevators and Lavatories

The building is at present equipped with three elevators, but provision has been made for two more. The capacity of each elevator is 6,000 pounds, and the platform is 7 by 11 feet. All the elevators run from the basement to the top floor and are electrically driven. Each elevator at each floor is equipped with a rising gate, and the openings are protected with steel rolling shutter doors. The elevator and stair wells are of brick and steel construction. All floors and landings are of concrete on steel and have a mastic ashphalt finish. The stairway construction is steel trough, with concrete filling and mastic treads. One notable feature in the construction is the absence of foundations for supporting the heavy mill lines and other heavy machinery on the first floor. The machines are supported on steel beams carried on the main columns of the building. This method of construction gives a clear and unobstructed basement.

Considerable attention has been given to the welfare of the employees in the matter of lavatory accommodation. Lavatories and toilets are provided on each floor, being located on the stairway landings and in separate rooms. The lavatories are provided with hot and cold water, while liquid soap is piped to each bowl from a small overhead tank. Paper towels are provided in preference to the old-fashioned and unsanitary roller towel.

A well-equipped machine shop occupies a part of the main floor at the west end. The equipment installed includes a general line of machine tools suitable for effecting repairs and making parts for the machinery in the factory, the company being independent of outside help in this respect except for castings or heavy work.

Transmission Equipment

The transmission equipment in the factory was supplied and installed by the Dodge Mfg. Co., Toronto, while the ball bearings on the line shafting are of the Chapman type, there being over one hundred sets of ball bearings of one size, in addition to others of varying sizes.

Fire Protection System

A sprinkler system is installed throughout the plant connected to the overhead tank and fire pump. Branches from the system are taken off from four separate risers at different points in the building, each riser having a control valve. There are 6 sprinkler heads to every 20 feet square bay on all floors. The entire system including valves is painted red, all other piping being black. The sprinkler system was installed by

FIG. 2. SECTION OF MAIN FLOOR SHOWING WARM UP MILLS AND CALENDERS. NOTE CONSTRUCTION OF FLOOR AND LOFTY INTERIOR.

the H. G. Vogel Co., Buffalo, N.Y. The tank for the sprinkler system has a capacity of 75,000 gallons and was constructed by the Chicago Bridge & Iron Co., Bridgeburg, Ont.

The power house is one of the outstanding features of the Goodyear factory, embracing as it does some unusually fine equipment. The building is of large proportions and substantial construction while the architectural features are also noteworthy. In the layout, provision has been made for installing additional units and also for making extension to the building when necessary without interfering with the plant as installed at the present time.

Constructional Features

The building is of steel and brick construction and is divided into four sections, namely, the boiler room, pump room, motor generator room, and transformer room. These rooms have the following dimensions:—Boiler room 58 feet by 88 feet; pump room 40 feet by 66 feet; motor-generator room 36 feet by 66 feet, and transformer room 22 feet by 66 feet. This gives the building a total length of 156 feet and a width of 88 feet at the boiler room end and a width of 66 feet for the remainder of the length. The boiler room is 40 feet high, as are also the others.

The windows are of steel sash, are arched in semi-circular form which improves greatly the general appearance of the building. The roof is composed of 2-inch concrete reinforced with ferro-inclave, laid on steel purlins, the ferro-inclave being plastered on the underside. On top of the concrete are laid 2 inch boards which in turn are covered with 4 ply felt roofing, the pitch for same being poured not mopped. This again is covered with slag. The building is fireproof, while the wood over the concrete prevents the roof from sweating.

The basement under the boiler room is 16 feet deep. Two of the basement walls while acting as retaining walls are constructed of brick to allow for future extensions in both these directions. The boiler foundations are of concrete, 16 feet deep. They are constructed so as to take care of expansion and contraction, expansion joints being provided as in the case of the boiler setting. The stack is built in one bay of boiler room, the gases being led to it through a smoke duct in boiler foundations. The stack is 250 feet high and 15 feet internal diameter at the top. Its foundation is of reinforced concrete 36 feet square and designed for a maximum load of 3 tons per sq. foot.

The stack is constructed of radial perforated brick laid with strong cement lime and forming a very strong bond. The perforations form a dead air space around the chimney, insulating the hot column of rising gases on the inside from sudden changes of temperature of the outer air, resulting in a maximum draft under practically all conditions. The stack is large enough to take care of a duplicate boiler installation or a total of six boilers. The stack was constructed by the Custodis Canadian Chimney Co., Toronto.

Equipment Contractors

The power house and its equipment layout were designed by F. H. Breor, chief engineer for the Goodyear Co. Robert L. Finlay is engineer in charge. The entire installation of pumps with one exception were supplied by Epping-Carpenter Pump Co., Pittsburg, Pa. The high pressure piping and fittings were supplied by the Walworth Co., Boston, Mass.; pipe covering by the Canadian H. W. Johns-Manville Co., Toronto; pressure reducing valves by Kiely & Mueller Co. through Arthur S. Leitch Co., Toronto; and steam traps by V. D. Anderson Co., Cleveland, O. The valves are principally by the Lunkenheimer Co., Cincinnati, Ohio. The Crane Co., of Chicago, also supplied some valves. The auxiliary steam turbine and generator set was supplied by the Canadian General Electric Co.

The entire electrical equipment in the power house was supplied and installed by the Canadian Westinghouse Co., Hamilton, Ont. The International Engineering Works, Amherst, N.S., built and installed the boilers. The stokers were supplied by the American Engineering Co., Pittsburgh, Pa.; the fan by the American Blower Co., Detroit, Mich.; and the ash conveyor by the American Steam Conveyor Co., Chicago. All the piping was installed by Bennett & Wright, Toronto. The travelling crane was made by the Northern Crane Wks., Walkerville, Ont. The building was erected by the Dominion Construction Co., and the rolling doors in each of the rooms were supplied by the A. B. Ormsby Co., Toronto. The "Venturi" meter was supplied by the Allen General Supplies Ltd., Toronto.

Boiler Installation

The boiler installation comprises two 600 h.p. Edgemoor type water tube boilers built and installed by the International Engineering Works, Amherst, N. S. Provision has been made for another unit of same capacity when required. They are among the largest boilers ever built in Canada. A feature of this type of boiler consists in the three longitudinal drums which run into the box header. Another point of interest is the distance between the tubes and grate. The first row of tubes is 12 feet from the grate allowing more than the usual amount of space for combustion so that the gases will be thoroughly burned before coming in contact with any part of the boiler having a lower temperature which would create condensation and thus cause smoke. The boilers have flanged headers and seamless steel tubes,

FIG. 3. SECOND FLOOR. FIRE CONSTRUCTION DEPARTMENT WITH STOCK TABLES ON THE LEFT AND BUILDING MACHINES ON THE RIGHT.

FIG. 4. WEST END OF SECOND FLOOR WHERE TIRES ARE CURED AND VULCANIZED.

the latter being 4 inch diameter and 20 feet long. The boilers are designed for a working pressure of 200 lbs. per square inch, but are only operated at 175 lbs. They are equipped with Lunkenheimer non-return stop valves, there being a runway with chainblock overhead to handle the valves. Access is gained to the top of the boilers by means of a steel stairway. Reference to the piping is made under another heading. The boiler fronts are equipped with rolling steel doors supplied by the A. B. Ormsby Co.

Mechanical Stoker Installation

The boilers are equipped with Taylor power dump stokers supplied by the American Engineering Co., Philadelphia, Pa. This is a seven retort machine with a continuous overload capacity of 200 per cent. boiler rating and a maximum peak load capacity of 250 per cent. for four hours; the maximum operating economy is obtained at approximately 150 per cent. boiler rating. The Taylor is a gravity underfeed stoker with inclined fuel bed, and has a hinged dump plate operated by a steam cylinder located underneath. The coal from the hopper is fed into the magazine or retort from which two cylindrical rams driven by connecting rods from a crank shaft, and assisted by gravity, push it into the furnace at an angle to the fire surface. The upper ram shoves the coal outward and upward, distributing it in the coking zone. The lower ram working with the upper acts similarly, but instead of forcing in fresh coal, it impels the fuel bed and the refuse toward the dump plates in the rear.

The necessary air to support combustion is furnished by a power-driven fan located in the boiler room basement. The fan which is direct connected to two vertical steam engines, was supplied by the American Blower Co., Detroit, Mich. The air is driven through ducts to the wind box, thence into the tuvere boxes, and in turn through the fuel bed. The driving unit for the fan drives both the fan and speed shaft, which, in turn, drives a crank shaft which actuates the rams. The crank shafts are in sections; there being a section for each pair of rams, while each group of sections is driven from its own gear box. Since the same driving unit operates both stoker and fan, a change of speed simultaneously changes both rate of feeding coal and rate of supplying air.

Ash Ejector

A Griffin ash conveyor is installed along the front of the ash pit, which conveys the ashes to a pit outside the building. The conveyor which is operated by steam jet was supplied by the American Steam Conveyor Co., Chicago, Ill.

Pump Room

In the pump room are installed all the pumps required for the various services, also the feed water heater, and air compressor. The layout is as follows:—On the west side are two hot well pumps and feed water heater, a boiler feed pump, two high pressure hydraulic pumps, balancing tank and the accumulator. On the opposite or east side are the fire pump, booster pump, two low pressure hydraulic pumps, air compressor and vacuum pumps. All the valves in the piping system connecting the pumps are located in the basement, and are controlled from floor stands in the pump room. The ten ton overhead Northern travelling crane installed here is operated by hand from the pump room floor. All the piping, both steam and water, is carried under the ceiling of the basement under the pump room. The basement is 12 feet high allowing ample head room. At one end of the basement is a sump for waste water and drainage. The sump is equipped with a bilge pump for delivering its contents into the sewer. The pump is a 3-inch Yeoman Bros. submerged centrifugal, driven by a Canadian Westinghouse motor.

All clean returns from the factory services, traps, etc., discharge normally into the hot wells. Make-up water is supplied to the hot wells to make up for losses. Water is pumped from the hot wells by two 7½ x 8½ x 6 in. pumps located near the feed water heater in the pump room. The hot wells are cross connected so that either can be used independently of the other. A 5 x 8½ x 6 in. Epping-Carpenter duplex pump is installed in the basement for delivering clean returns from a sump to hot wells, in case difficulty is experienced at any time in raising returns direct to hot wells. There is a tank on the main floor for settling sand and sediment in the raw water from the lake that goes to the presses. This tank is at a sufficient elevation to put a head on the pump sections. The tunnel through which all the piping is carried to the factory runs from this basement to the factory building basement.

FIG. 5. TWO 600-HORSEPOWER ROBB WATER TUBE BOILERS WITH TAYLOR STOKERS.

Returning to the pump room there are two 7½ x 8½ x 6 inch Epping-Carpenter duplex horizontal pumps for drawing from the hot wells and discharging to the feed water heater. The 4,000 h.p. feed water heater was built by Warren, Webster & Co. Camden, N.J. Next in the line is a 3 inch, 4-stage Epping-Carpenter centrifugal boiler feed pump which supplies water to the boiler from the heater at 225 lbs. pressure. This pump is direct connected to a 35 h.p. Can. Gen. Electric a. c., 2200 volts, induction motor. In the line between this pump and the boilers is a 3 x 1 inch, type M register-indicator-recorder. "Venturi" meter supplied by the Builders Iron Foundry, Providence, R.I., through the Allen General Supplies, Ltd. On the same side of the pump room are installed two Epping-Carpenter 10 x 2 x 2 inch duplex, horizontal, outside packed, pot valve, steam driven pumps. These supply water at 1,500 lbs. pressure to the hydraulic presses in the factory, and operate in conjunction with an accumulator having an 8 inch ram of 8 feet stroke. The valves and fittings on these pumps are Crane Co. make. The balancing tank for the low pressure hydraulic pumps is situated on this side. It is 42 inches in diameter by 12 feet high.

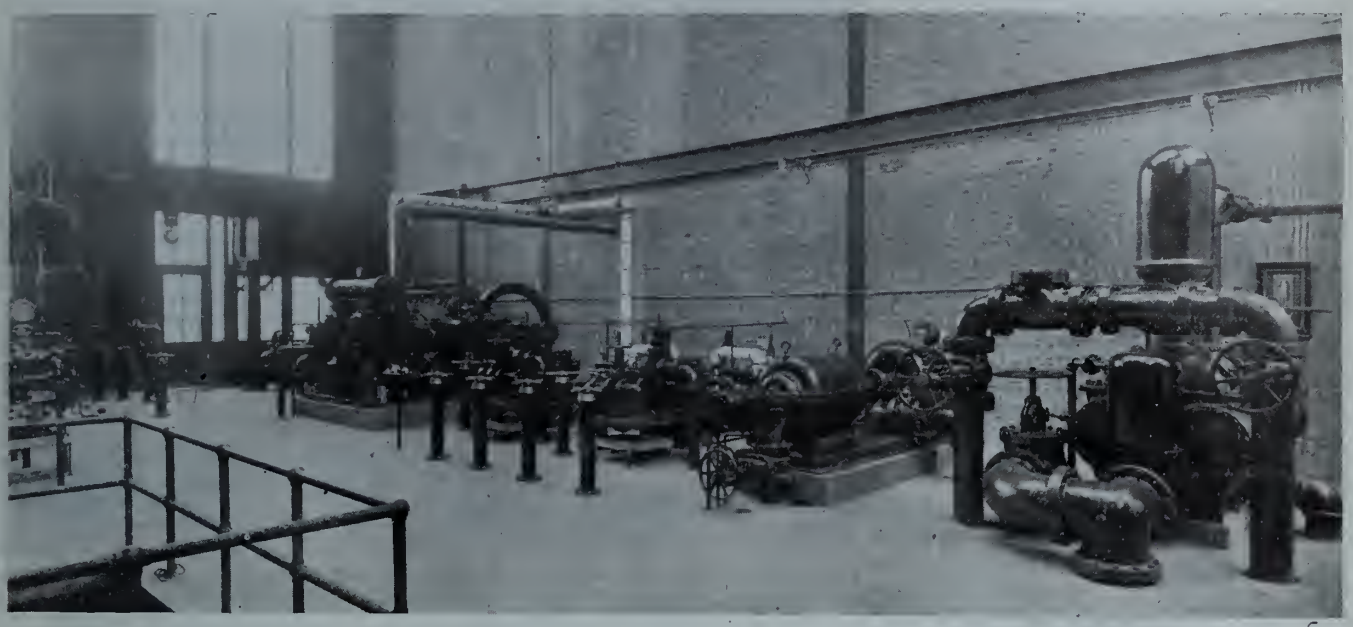

FIG. 6. EAST SIDE OF PUMP ROOM SHOWING, FROM RIGHT TO LEFT, FIRE PUMP, BOOSTER PUMP, LOW PRESSURE HYDRAULIC PUMPS, AND AIR COMPRESSOR.

Fire Pump and Air Compressor

On the east side of the pump room there is installed at the south end a Blake-Knowles 18 x 10 x 12 inch, horizontal, duplex, Underwriters' fire pump, having a capacity of 1,000 gallons per minute. This pump supplies the sprinkler tank and fire system lines for the factory. The next unit is a booster pump for factory water supply, or alternatively for the fire system. This pump delivers water at 125 lbs. pressure to the factory. It is a 6 inch, 3-stage Epping-Carpenter turbine unit direct-connected to a 150 h.p. Curtis steam turbine running at 1,500 r.p.m. Next in line are the pumps for supplying water at 225 lbs. pressure for the presses in the factory. There are two units for this service, both Epping-Carpenter make, of 12 x 6 x 12 inch, duplex, horizontal pot valve type. These pumps operate in conjunction with the balancing tank, but can also be used for boiler feeding in an emergency.

A Laidlaw-Dunn-Gordon air compressor is located on the same side of the plant. This unit is a 10 x 16 x 16 x 10 x 12 inch, cross compound steam driven, 2-stage machine, and delivers compressed air at 100 lbs. pressure throughout the entire plant. It also operates in connection with the balancing tank and a receiver, the pressure being controlled by a Fisher pressure regulator. The vacuum pumps for the heating system are installed at the north end and east side of the pump room. There are two of these pumps, both being Epping-Carpenter 6 x 10 x 12 inch units. They are controlled by a Mason regulator. The gauge board installed alongside the Venturi meter will have 14 Bristol gauges and recorders for steam, hydraulic and water service pressures, vacuum, etc. In the illustration showing the west side of the pump room, two steam lines will be seen. The one on the left hand is the 10-inch steam line for the factory, and the one on the right hand is the 8 inch line feeding the distributing header for the pumps.

Piping System

The piping system is one of the features of the power plant and a great deal of time and ingenuity has been expended on the layout. In designing the system, the principal objective of the engineers was to have the piping for the various services so installed that a tie-up in the factory would be practically impossible. To provide for all contingencies, the various pumps are connected up with the water mains in such a manner that if one pump fails another can be by-passed into the line; in other words, flexibility is the feature of the piping system. The water is pumped to the power-house from the lake by two 8 inch, 3 stage Bawden turbine pumps located in the municipal pumping station there. The water is delivered to the factory through a 12 inch main direct to the factory distributing system. This water, however, can be by-passed to a 200,000 gallon storage reservoir so that, in the event of the pumps at the lake failing, the factory can be supplied from the storage reservoir by means of a 6 inch, 3-stage turbine pump which delivers the water direct into the factory distributing system. One instance of the flexibility of the piping arrangement is the fire protection system. A Blake-Knowles Underwriters' pump can deliver water from the reservoir direct to the factory supply line or from the regular 12 in. supply line. In the event of the fire pump being out of commission, a turbine pump can be by-passed into the line, thus providing four alternative methods of suppling the factory fire system apart altogether from the overhead sprinkler tank.

Alternative methods of boiler feeding are also provided, either direct from the feed water heater, which is the regular way, or from either of two hot wells for which another pump is used, or from either or both the low pressure and high pressure hydraulic pumps. The piping system although complicated has proved thoroughly satisfactory in practice. A detailed description of the system would take up considerable space and would doubtless be confusing to the reader so a more general description only will perhaps better serve the purpose of this article. Taking the piping system as a whole, great credit is due Mr. Breor, the Goodyear Co. engineer who designed the

layout, and to Bennet & Wright, of Toronto, who carried out the work.

Steam Piping System

Taking the steam piping first, steam is received from the boilers by two 8 inch lines to the header. The header is 14 in. in diameter, of wrought steel, with wrought steel nozzles or branches welded to it by the oxy-acetylene process. The flanges are of cast iron and the header is 20 feet long. There is a 10 inch line to the factory, an 8 inch line from the header to the pumps and air compressor on the East side of pump room, and two 4 inch lines, one for the pumps on the West side of the pump room and the other line to the boiler room basement for the ash conveyor, fan engine, etc. The piping is designed for 175 lbs. per sq. inch working steam pressure with 100 degrees Fah. superheat.

The 10-in. line extra heavy steel pipe is carried under the pump room into the basement where the pressure is reduced from 175 lbs. to 100 lbs. by a Kiely & Mueller reducing valve. At this point the line leading to the factory is by-passed, and is equipped with an expansion joint, a steam separator, two Lunkenheimer valves, and an Anderson steam trap. From here the main steam line leading to the factory is carried through the tunnel to a point in the factory basement where the steam is distributed for the heating system and for factory purposes, such as heating, vulcanizing, etc.

A relief is installed at each regulating valve to prevent the pressure building up. The distributing line for the heating system is 6 inches on the high pressure or inlet side, and 12 inches on the low pressure or outlet side of the reducing valves. The pressure from the main line for the heating system is reduced from 100 to 30 lbs., and from 30 to 2 lbs. by Kiely & Mueller reducing values.

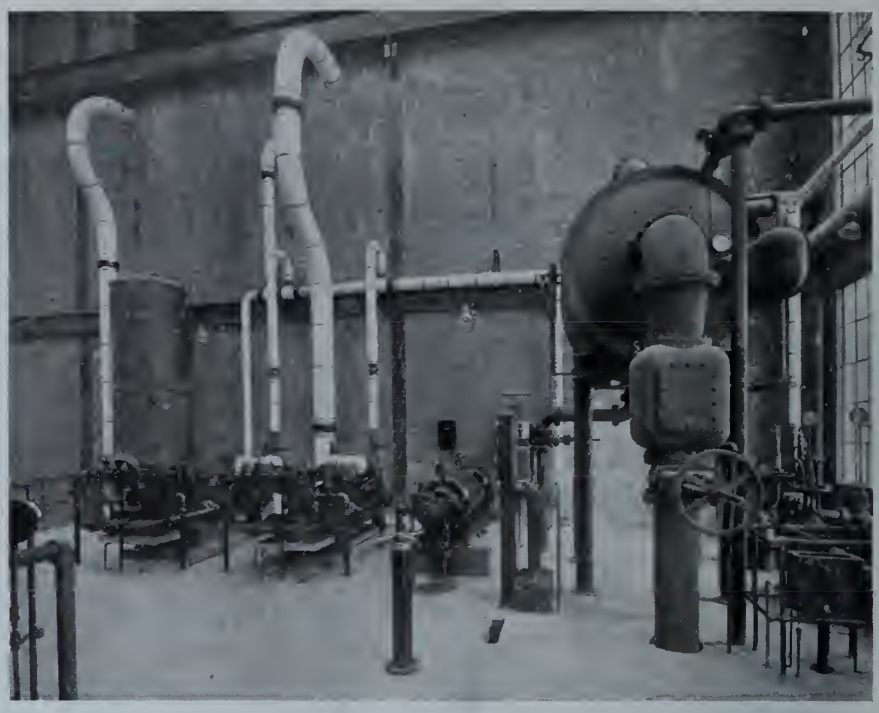

FIG. 7. WEST SIDE OF PUMP ROOM SHOWING BOILER FEED PUMPS, FEED WATER HEATER, AND HIGH PRESSURE HYDRAULIC PUMPS.

The 12-in. exhaust steam header is carried the entire length of the pump room basement and collects the exhaust from all the pumping units, and discharges into the feed water heater, or is by-passed to the atmosphere. The exhaust steam header is of standard steel construction with steel flanged fittings. The exhaust pipe from one pump and the by-pass from header consist of spiral riveted wrought iron pipe.

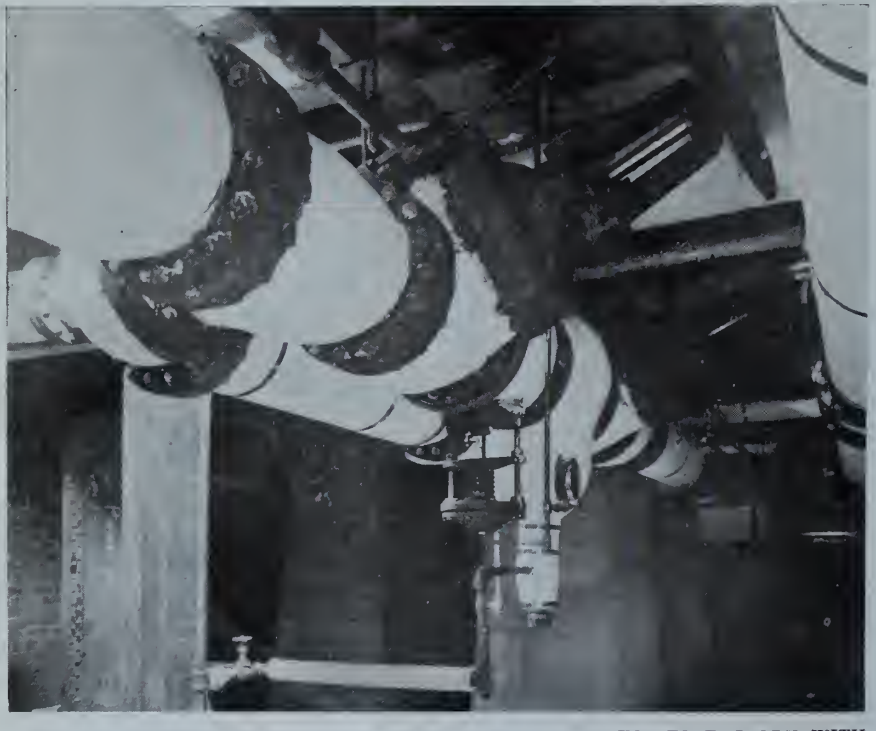

FIG. 8. PUMP ROOM BASEMENT SHOWING MAIN STEAM LINE TO FACTORY WITH SEPARATOR, REDUCING VALVE, AND BY-PASS PIPE.

All the fittings which carry boiler pressure are of cast-steel and have Vanstone joints, both fittings and bends being supplied by the Walworth Co., Boston, Mass. All the reducing valves were supplied by Kielly & Mueller, and the steam traps by V. D. Anderson & Co., Cleveland, Ohio. All piping carrying high pressure is covered with 85 per cent., 1½-in. sectional magnesia, with the exception of the tanks, vulcanizers, etc., which are covered with 85 per cent. magnesia block. The exhaust steam piping and low pressure heating line are covered throughout with 1-in. sectional air cell. All covering is painted with two coats of lead and oil, and is finished with brass bands, the whole presenting a neat and workmanlike appearance. The pipe covering was supplied by the Canadian Johns-Manville Co., and was installed by Bennett & Wright.

All the high pressure valves are cast steel and were supplied by the Lunkenheimer Co., as were also the non-return valves on the boilers. All clean returns from the factory discharge into two hot wells under the pump room floor. Make-up water is also supplied to the hot wells in sufficient quantity to take care of losses.

Hydraulic Piping System

The raw water which is pumped from the lake is carried in a 12-in. main to the pump room to supply the various pumps, tanks, etc., or direct to the factory supply main. A line is carried from the inlet main to a 6-in. turbine booster pump which supplies water to the factory for general purposes at 125 lbs. per sq. inch. A second connection goes to the fire pump, a third to the low pressure hydraulic pump, and a fourth to the boiler feed make-up water. A 250-lb. pressure line is carried from the low pressure hydraulic pump to the

presses in the factory, while another line carrying 1,500 lbs. pressure is taken from the high pressure pump, also to the presses. The high pressure service is used for operating the presses and the low pressure service for putting the presses in position for operating.

A 4-in., 50-lb. pressure line is carried to the factory for the plumbing system, while a 2½-in. suction line is taken from the 250 lb. water service line to the hydraulic pump which boosts the pressure to 1,500 lbs. A balancing line is taken from the balancing tank in pump room to obtain uniform pressure on the system. The high pressure pumps operate in conjunction with a hydraulic accumulator also located in the pump room. There is a 2½ inch line connecting the balancing tank with the air compressor. The material used in the low pressure lines is extra heavy steel pipe with cast iron fittings. For the lines carrying 250 lbs. and upwards, extra heavy steel pipe and cast steel fittings are used. Crane cast steel valves are used in the 1,500 lb. lines, and Lunkenheimer valves in the lines carrying pressures below this.

The Blake-Knowles fire pump delivers from the 12-in. intake supply line to the stand pipes in the factory and also to the sprinkler tank. It will also pump water from the storage reservoir to the fire system. The booster pump is connected up to deliver water to the factory for general purposes or to the fire system, taking the water from the incoming line or from the storage reservoir. The two low pressure hydraulic pumps are connected up so that they can be used for boiler feeding in case of emergency. All hydraulic returns are collected in a tank and returned to the pumps.

Heating System

The heating arrangements for the factory are on the low pressure vacuum return system which has been designed to give a temperature of 70 degs. at 10 deg. below zero, Fahr., with maximum wind pressure. In designing the system particular care had to be taken to allow for the large area of glass and somewhat high wind pressure on account of the exposed location of the factory. There is a total of approximately 40,000 sq. ft. of radiation. The building is warmed throughout with wall radiators placed below the windows, each radiator containing an average of 200 sq. ft. of radiating surface. On the supply end of each radiator is a Jenkins valve and on the return end a Dunham vacuum trap. The radiators are hung with special wrought iron brackets which are built into the wall. They are in two feet wall sections, are of new pattern, and were supplied by the Dominion Radiator Co., Toronto.

The distributing mains for the heating system are carried on the second floor ceiling, while risers take care of the third and fourth floors, with drop risers for the floors below. The vacuum return system is carried along basement ceiling to the tunnel and back to the vacuum pumps in the pump room. The roof monitors are taken care of by 1¼ and 1½ inch pipe coils, there being twelve coils containing 10,500 feet of pipe complete with headers, elbows and supports. The coils are arranged so that the entire bank can be cut off by a valve placed on the floor line. The pressure is reduced from 100 lbs. to 30 lbs. and then from 30 lbs. to 2 lbs. by reducing valves which are situated in the factory basement near the tunnel. The entire heating system was designed and executed by Bennett & Wright.

The original plans did not call for a steam heating installation in the power house as it was thought to be unnecessary. Owing, however, to the efficiency of the steam pipe insulation, it was finally found necessary to heat the building. In the power house there are 2,700 feet of radiation. The heating system is similar to that installed in the factory. The cement house and spreading house have a total of 1,500 feet of radiation, and the same system is installed in these two buildings as in the main factory building. The only variation is that the radiators were supplied by Steel & Radiation, Toronto, instead of by the Dominion Radiator Co.

Electrical Installation

There are a number of interesting features in the electric power and lighting installation. The company takes power from the Hydro System but considerable direct current power is also required for a number of the factory motors. The equipment in the motor generator and transformer room will be taken together in the description given below, being naturally dependent upon one another. In the motor generator room, provision has been made for an additional unit which may be installed in the near future. Runways have also been provided for an electric traveling crane which however has not as yet been installed. The accompanying illustration shows the switchboard gallery which is 14 feet wide and extends the entire length of the room. It will also be observed that there is a rolling door for each room; these were supplied by the A. B. Ormsby Co., Toronto.

Transformers and Switches

The plant receives 3 phase 25 cycle power at 2200 volt through an overhead line from the Hydro sub-station a short distance from the company's power house. The line enters the building at the transformer room. The system is protected by a set of Westinghouse type AK electrolytic lightning arresters. These are mounted on a gallery about 25 ft. from the floor. Disconnecting switches are also here provided for cutting off the entire supply. On the main floor of this room there are installed four 150 KVA. O. I. S. C. transformers, 2200/550 volts. Three of these are ordinarily used connected in delta, the fourth being a spare unit which can take the place of either of the others in case of breakdown. On a pipe structure immediately above the transformers there is mounted a set of disconnecting switches for both the high and low tension side of each transformer, and, over the spare transformer, these switches are double throw and connected in such a manner that the spare transformer can be put into service by simply closing the proper switches.

Directly opposite the transformers in the same room is located the 2200 volt switch structure. This consists of the usual pipe framework with a laminated copper bus running along the top. Beneath this are mounted all the electrically operated remote controlled oil switches which control the various outgoing 2200 volt feeders to the factory, and also the primary of the transformer bank. Between the oil switches and the bus there is a set of disconnecting switches on each circuit, and at the end

FIG. 9. MOTOR-GENERATOR ROOM WITH SWITCHBOARD GALLERY AND 550-VOLT SWITCH STRUCTURE UNDERNEATH THE D.C. BOARD AT FAR END.

of the structure the main incoming line switch, which is also electrically operated, is located, likewise the disconnecting switches.

There is also mounted adjacent to this structure another set of Westinghouse type AK electrolytic lightning arresters which are connected directly to the 2200 volt bus. All series transformers are connected in on the load side of the circuit breakers and immediately above the potheads on the end of the lead covered cables. The cables pass from here down through the floor into the underground duct system, which will be spoken of later.

A.C. and D.C. Switchboards

Next to the transformer room there is the motor-generator room which also contains the operating gallery on which is mounted the nine-panel a.c. switchboard, and five panel d.c. switchboard, both of Westinghouse manufacture. The material used on both these switchboards is black marine slate, having a total height of 7 ft. 6 ins., composed of one panel 25 ins. high, and another 5 ft. 5 ins. high, supported on angle iron frame work. The width of the panel varies according to the amount of apparatus mounted thereon, but none are less than 20 ins. wide. The thickness of the slate is 2 ins. and each panel has the edges of the slate beveled. The a.c. board controls all the 2200 and 550 volt circuits and the incoming line switch. As all these switches are remote controlled and electrically operated, only the controls and the indicating lamps are mounted directly on the switchboard.

A totalizing panel is provided which contains a Westinghouse graphic recording wattmeter, graphic recording frequency meter, graphic recording power factor meter, and graphic recording voltmeter. At the left-hand end of this board, on a swinging bracket, are mounted a voltmeter and an indicating power factor meter, the voltmeter being arranged so that it can be plugged on to any one of the three phases, and the power factor meter arranged so that by inserting a plug into a receptacle provided on each one of the feeders, the power factor of that load may be read. The relays protecting all the circuits on this board are Westinghouse type B shunt trip, and are located on brackets at the back of the board.

Motor Generator and Connections

In a plant of this kind it was found advisable to use direct current motors on the calenders, and for supplying this load there has been installed a Canadian Westinghouse motor-generator set. This is a three-bearing machine, consisting of a 510 h.p., self-starting synchronous motor, 3 phase 25 cycle 2200 volt, direct connected to, and on a common bedplate with, a 350 k.w. 230 volt 3-wire d.c. generator. The speed of the set is 750 r.p.m., and there is a 6 k.w. exciter mounted on the end of the shaft for exciting the synchronous motor. Balance coils are provided capable of carrying unbalanced load up to 50 per cent. of the generator capacity. The d.c. leads from the generator are carried through conduit up to the back of the d.c. switchboard on the gallery, where the usual switches and circuit breakers are provided.

The starting panel for the synchronous motor forms part of the d.c. switchboard. On it are mounted two controllers and three signal lamps, which work in conjunction with three electrically operated oil switches on the switch structure immediately below the gallery. This panel also mounts relays, a field switch, and two ammeters, one in the field circuit of the synchronous motor, and the other in the primary circuit. To the right of the d.c. generator panel there are two d.c. feeder panels consisting of 800 amp. carbon circuit breakers, ammeters and knife switches. The last panel on this switchboard is for controlling a 25 k.w., 125 volt, General Electric Co., turbo-generator, which is used for emergency lighting in case the power should be off. On a swinging bracket at the right-hand end there is mounted a 300 volt d.c. voltmeter.

Switch Structure Details

The switch structure, which is mentioned as being underneath the switchboard gallery, in addition to mounting the oil switches for the synchronous motor, also has mounted on it the 550 volt electrically operated oil switches. These are fed from an overhead bus through disconnecting switches, and the entire structure is very similar to the 2200 volt structure in the transformer room. Altogether there is a total of 18, either 2200 volt or 550 volt Westinghouse type B electrically operated remote controlled oil switches in this plant.

By the use of these switches the Goodyear Co. have been able to concentrate all their controllers on a comparatively small switchboard which would not have been possible had they mounted the oil switches directly behind the switchboard panels as is so often done in installations of this kind. On all parts of the electrical equipment there has been provided ample room for future extension. Both switch structures can be extended a considerable distance; and there is room for two more motor-generator sets as well. Both a.c. and d.c. switchboards can be extended in either direction, and the a.c. switchboard is even now provided with two blank panels which can be equipped with instruments and controllers when the occasion arises.

All the cables leaving the power house are three-conductor, cambric insulated, and lead covered. These pass through an underground duct system consisting of about sixty 3-inch fibre conduits, to a brick cable vault located at about the centre of the factory building in the basement. From here the various cables are distributed. The 2200 volt cables to the large motors run direct through in iron conduits. The other circuits, consisting of 550 volt power and the direct current circuits change to rubber insulated braid covered cable, run in iron conduits, to the various machines or distributing points.

FIG. 10. VIEW OF TRANSFORMER ROOM. 2200-VOLT SWITCH STRUCTURE ON THE RIGHT AND TRANSFORMERS ON THE LEFT.

Lighting Details

The lighting of the factory is taken care of by three 35 k.w. oil insulated single phase transformers, located in a sub-station in the basement of the factory. In this room there is also a 2200

FIG. 11. BACK OF D.C. SWITCHBOARD SHOWING ARRANGEMENT OF BUSES.

volt oil switch for controlling the primary, and a number of knife switches and fuses for controlling the secondary circuits. This apparatus is mounted on two black marine slate panels of standard height and dimensions. A 6-wire cable bus is run from the low tension side of the transformers over the top of the switchboard panels, and connected to the laminated copper bus which distributes power to the various lighting circuits.

Factory Motors and Equipment

The various lines of mixing mills, warming up mills and washing mills in the factory are driven by Westinghouse type CCL squirrel cage induction motors, 3 phase, 25 cycle, 2200 volt, 500 r.p.m., 2-bearing pedestal type, there being three of 400 h.p., one of 300 h.p., and one of 200 h.p. These are each direct coupled to a reducing gear by means of a Cutler-Hammer magnetic clutch coupling, which in turn is connected with a safety switch located over each mill, so that in case of accident the operator may by tripping the safety switch disengage the magnetic coupling which operation also sets two magnetic brakes, one connected to the motor shaft, and the other to the reducing gear shaft, and also opens the motor switch, so that the whole outfit is immediately brought to a standstill.

The starting panels for each of these large motors are in each case located just a few feet away from the motor. In addition to a double-throw starting oil switch for the motor, and a double-throw oil switch for reversing the motor in case of necessity, there is also mounted the relay apparatus for controlling the brakes and clutch couplings. An ammeter connected in the primary circuit of the motor completes the equipment of these panels. The apparatus at the back of the panels is neatly enclosed in a steel housing, with a ventilator at the top. The auto-transformers and cable terminals, etc., are also mounted within this housing.

For driving calenders there are provided three 75 h.p. variable speed direct current motors. These are of steel frame pedestal type construction, and are equipped with interpoles. They are operated from the 3-wire 115-230 V. system and have a range of speed from 375 to 750 r.p.m. The various speeds on the lower range are obtained by connecting the motor to the 115 volt leads, and by using control. The higher speeds are obtained by connecting the motor to the 230 volt leads, and also using field control. The control panels, which are of Cutler-Hammer manufacture, are mounted directly beside the calendars, and are operated from a master controller mounted right on the calender frame.

In addition to the equipment mentioned above, there have been installed at various points in the factory, a large number of smaller sized induction motors, mostly of Canadian Westinghouse manufacture. Some of these are started with the Westinghouse type K auto-starters and some of them in the smaller sizes are provided with a Westinghouse type H oil circuit breaker.

In case of the failure of supply from the Hydro, the 25 kw. turbo generator is connected through 3 pole d.t. automatic switches to feeders on all floors to supply necessary lighting to complete any operations requiring immediate attention such as vulcanizing, etc.

The main equipment was supplied and installed by the Canadian Westinghouse Co., Hamilton, Ont.; the bus bar equipment by the General Devices & Fitting Co.; the wires and cable by the Standard Underground Cable Co., Hamilton, and the Northern Electric Co., Montreal. The wiring for lighting and 550 volt power was installed by G. J. Beattie, Toronto.

Electric Lighting Installation

The electric installation for the lighting of the factory is fed from the three 40-k.w. single-phase transformers already mentioned, these being connected in double delta to obtain a 3-wire, 230-115 volt, single-phase system.

From the switchboard in basement sub-station, two sets of three wire mains run to each floor in conduit, changing into open wire at second bay on either side of the centre of the building. The three wires run the entire length of the building on E. E. E. bus insulators mounted on beam clamps to lower web of each I beam, and slack is taken up by strain insulator and J bolts at each end. On the mains in the basement is the only place where conduit has been used, junction boxes being placed at short intervals to allow of alterations and additions.

The circuits are fed from 4-circuit, 2-wire fuse cabinets placed about 10 ft. from the ground on the columns (to prevent unauthorized persons tampering with fuses). From the cabinets the branch circuits are run in conduit to centre of distribution of each circuit, changing into cleat wiring, split knobs mounted on Universal beam clamps, being used to support the wiring as it passes across the I beam from bay to bay; this method of wiring gives a very flexible arrangement, allowing alteration of position of lights to be made quickly and economically.

Nitrogen lamps of 100 watts, with Abolite shades and shock absorbers, have been used in basement, second, third and fourth floors, while 200-watt nitrogen lamps, with suitable shades, are in-

FIG. 12. EXTERIOR VIEW OF FACTORY AND POWER HOUSE, WEST END.

stalled on first floor, which has a high ceiling. General illumination has been used mostly throughout the factory, except in spaces set apart for tire manufacture, etc., in which group lighting suitable to the various operations has been installed.

In the power house, owing to the height of the roof, 500-watt nitrogen lamps, with distributing shades, are utilized, with the addition of bracket lights around walls in generator room, pump room, and boiler room. Approximately 24 miles of rubber-covered wire and cable have been installed, together with seven hundred 100-watt, one hundred 200-watt, and twenty-five 500-watt nitrogen lamps of Westinghouse manufacture.

THE INVENTION OF THE STEAM HAMMER

NASMYTH invented his huge steam hammer to forge the paddle shaft of the Great Britain on Nov. 24, 1834, but Brunel recommended the screw propeller after the trials of the Archimedes by Francis P. Smith, and this upset all the arrangements for the use of the hammer, but the iron trade which had been slack for some time revived and Nasmyth used and patented his hammer in 1842 after his return from France. The hammer was so accurately made that he showed the Lords of the Admiralty at Devonport Dockyard, how a blow could be made so gentle as to crack the end of an egg placed in a wine-glass, as if done by an egg-spoon, and the next blow so violent as to rattle all the china in a home a quarter of a mile distant.

Another of Nasmyth's inventions was riveting by compression. One wet wintry Sunday afternoon he went to his workroom to perform some repairs to a small stone which required to be riveted, and as the noise of riveting might be heard he solved the difficulty by using the jaws of his bench vice to press in the hot rivets. This system of riveting was long afterwards patented by Smith of Deanston, with William Fairbairn of Manchester. It is extensively used in boilers, girders, and all other wrought-iron structures where sound riveting is absolutely essential, and by hydraulic power a considerable portion of iron shipbuilding is carried out by the silent squeeze system in place of hammers. When Nasmyth continued the silent and very effective method of riveting he named it "The Sunday Rivet."

MAN POWER BIGGEST FACTOR IN INDUSTRY

WHAT is going to happen if the output of steel is not increased? The fate of the war depends largely upon the steel production of the United States, and the out-turn is being seriously retarded by lack of fuel, iron, transportation facilities and labor.

The seat of the trouble which is hampering production at this time is labor. There are not enough men to man the steel plants. There is also not sufficient fuel to operate them for the same reason, and the facilities of transportation have proven entirely inadequate to the extra strain. The consequence has been that production instead of increasing is declining, and the out-turn of some mills is reported to have been reduced to 50 per cent. of normal capacity.

As for iron, the outlook is still more serious. The lack of man power is holding up production of ore, of fuel, and consequently of iron and steel. In the Eastern market recently there were inquiries for upward of 25,000 tons of basic and foundry iron. The great bulk of this demand must disappear because there is nothing with which to satisfy it. It is estimated that of the tonnage asked for probably not more than 5,000 tons will be found available for distribution.

The inquiries are for large and small lots for delivery from now to next July. The furnaces are also growing cautious about extending their engagements for next year, as they are already well sold up and behind on their present contracts for the year. Steel makers and foundry men are clamoring for iron all over the country, and the market has probably never before been subjected to such a combing process with so little tangible result. It is well for industry in general that the price is fixed or the market would undoubtedly be thrown into an unprecedented state of panic.

PRECAUTIONS NECESSARY FOR THE MAINTENANCE OF CRANE RAILWAYS

OUTSIDE crane runways seem to be less rigid than inside runways, possibly because of the fact that the building itself provides some support and thus gives more rigidity to the columns or uprights. Outside runways are also exposed to all conditions of weather, and for this reason as well as because of the constant strains and vibrations, they should receive careful inspection. In case defective members are observed they should be immediately replaced or repaired. Any corrosion or rusting that is observed should be checked by scraping or cleaning off rust and applying a proper protective coating. Runaways that have been in service for a number of years often sway quite noticeably, and sometimes to such an extent that the additional stresses thus produced are dangerous. If this condition exists repairs should be made or reinforcements should be applied, sufficient to restore the runway to its original strength and rigidity.

Effective safety inspection would prevent many of these dangerous conditions, and it should be thorough, regular, and careful. The inspector should not only submit recommendations for the safeguarding of the machines, which is one of his special duties, but he should also consider the possible failure of weak crane structures, spreading or creeping rails and columns, uneven settling of column foundations, and any other trouble that might disturb the proper alignment of runway tracks.

MORE FUEL OIL FOR STEAMERS

AN important change which has been comparatively lost sight of owing to the stress of war conditions is the increasing use of crude oil as fuel for steamships. Without a great deal of publicity having been given to the fact, a not unimportant portion of the American merchant marine has been turned into oil burners. The navies of the world, of course, have been using oil as fuel much longer than the merchant services. In this connection it may be noted that at a recent conference held at Washington between representatives of the American and British governments. Standard Oil officials and the Shipping Board, an ample supply of oil for the British navy was assured.

The chief advantages claimed for oil as fuel are a saving of bunker space in the ship and a saving of dead-weight. Up to comparatively recent years the drawback has been the price of oil, but with the unprecedented enhancement in the price of coal which war conditions have brought with them the economic opportunity to use oil has presented itself. Speaking generally the increase in the Texan, Mexican, and Californian oil supply which has taken place during recent years has made possible a greater use of oil for generation of steam on ships. Hitherto oil was usually too valuable to be used in ships furnaces.

Particularly on the Pacific Coast and in trade with the Orient has the war promoted the use of oil as fuel on ships, the source of supply in the Gulf region and California being relatively near at hand.

Five steamers now in course of construction for the New York- Valparaiso service are to be oil burners. Eighty per cent. of the Standard Oil steamers now afloat are equipped as oil burners. The Southern Pacific Railway, which has oil fields of its own, has been the leader in this country in the use of oil fuel for locomotive engines. In 1915 the company had 1,927 oil-burning locomotives out of a total of 2,046 engines. The Southern Pacific is also using oil as fuel for its steamers to a very considerable extent.

The Luckenbach Steamship Co. has a couple of oil-burning steamers. There was launched last month at the yards of the Fore River Shipbuilding Co., Quincy, Mass., a large oil-burning freighter of 10,000 tons dead-weight intended originally for the Luckenbach Steamship Co., but now taken over by the Government. The fuel oil is carried in the double bottom and in the forward and after peak tanks.

The Atlantic, Gulf & West Indies Steamship Lines have seven or eight oil-burners. Most of the newer ships have been equipped to use liquid fuel, the policy being to build all new ships with facilities for the use of either coal or oil. The Munson Line has two or three oil burners of 7,500 tons dead-weight, and other American companies have one or more vessels equipped in this way, as for instance the United Fruit Co. Some of the Cunarders will also be oil-burners.

Comparison of Working Costs of Principal Prime Movers*--II

By Oswald Wans

High thermal efficiency does not necessarily imply commercial superiority. Available data are seldom complete and render difficult the justification of claims and working costs advanced by advocates of respective prime movers. The engine of lower thermal efficiency may, therefore, under certain conditions, be the sounder proposition commercially.

THE quantity of lubricant necessarily varies widely in practice, even in similar engines, due partly to the differences in manufacture and to the care or negligence on the part of the attendant. To cover amply these factors, the charges should be of a liberal nature.

The accompanying curves, Fig. 4, give representative consumptions for new oil, no allowance having been made for filtering and re-using the oil. The saving effected by filtering is worthy of consideration, for it is possible by this means to reduce materially the oil bill. It should be noted, however, that filtered oil cannot be recommended for use in cylinders, unless enriched by about 30 per cent. of new oil. It will be observed that as the total quantity of oil is given, it must include both cylinder and bearing oils. For internal-combustion engines, it is customary to use one grade for both purposes, whereas two qualities are usual for steam-engines in which approximately one-third of the total quantity will be required for the cylinders and that remainder for bearings, etc. The adoption of one grade of oil has a practical advantage in preventing the use of the wrong oil for, say, the cylinders, a mistake likely to have serious results in an oil or gas engine.

Water Supply

In many localities a plentiful and gratuitous water service is not available, and the cost of the necessary supply becomes a matter of moment. With a free and suitable supply the water may be returned, directly after use, to the source, thus obviating the cost of a cooling plant. Frequently, however, the local charges render necessary a closed system whereby, with little loss, the water can be used repeatedly. For the smaller internal-combustion engines, up to 50 b.h.p., cooling tanks are very general, but for larger powers a cooler, of, say, the tower type, becomes necessary. The tower cooler is equally applicable for cooling condenser water and possesses the advantage of simplicity and low cost, but owing to its bulk is not always adaptable. When the requisite space is not available, a more costly form of cooler may be a necessity, but such cases are not general and must be considered individually.

In the Expenditure Curves, Fig. 1 (page 309), the cost of a cooling tower is included for international-combustion engines above 50 h.p. and for surface, but not jet condensing steam-engines. In the latter case it is assumed that the water is run to waste. The water lost by evaporation, in passing through the cooler, may be taken as 5 per cent. of the total water in circulation.

There may be a further loss due to leakages, but in a well-kept installation the loss on this account is negligible. This cooler loss holds good for steam-engines and internal-combustion engines, but there is a further loss in a suction-gas plant in the water required for supplying steam to the gas-producer and in the effluent from the cleaning plant. The former water is of course not recoverable, and the latter can be and is sometimes used several times before disposal. Unless special provision is made, the water is prone to foul the circulating pump and pipe-lines, and, when ultimately disposed of, is apt to arouse suspicion in the municipal mind owing to its more concentrated nature, and this applies particularly to wood refuse fuel.

Often the cleaning water can be taken continuously from and returned to a neighboring pond or river without charge. It may be remarked that the effluent after once passing through the cleaning plant is of a harmless nature, and if turned into a sewer or a river all traces of tar must be removed, as this appears to be the bete noire of local authorities.

The following table (page 342) gives the total quantity of water in service and the make-up water necessary to replace the cooler and cleaning plant losses. The latter quantities only need be considered in working costs, for the cost of the initial supply of water is negligible.

Sundry Stores

The payments arising from these items are small, and are generally covered by a charge of 0.01d. per rated b.h.p.-hour for any of the prime movers under consideration.

Labor

The charges under this heading should include not only the attendant's time during running hours, but also that needed to clean, grind in valves, etc., and generally to keep the installation in good condition. In the case of steam and suction-gas plants the time spent in handling the fuel and removing the ashes must be covered. The attendance time is fairly uniform for similar installations, and generally speaking is on a minimum basis. Usually it is not necessary to employ highly skilled labor, nevertheless sufficient should be paid to command the services of the intelligent

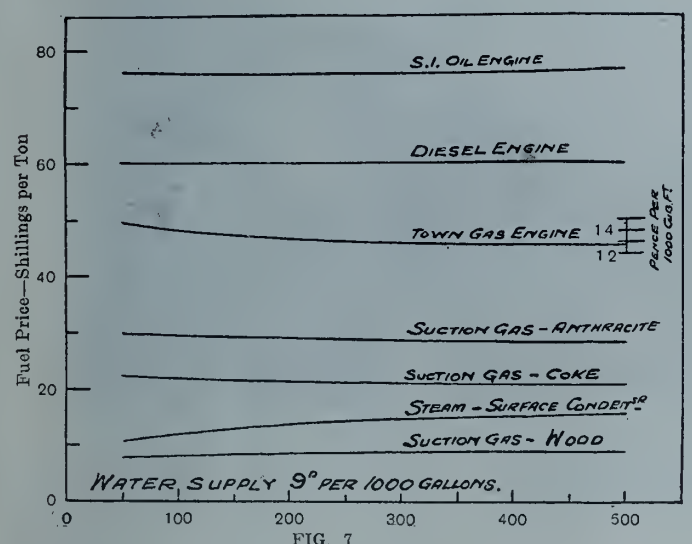

FIG. 7

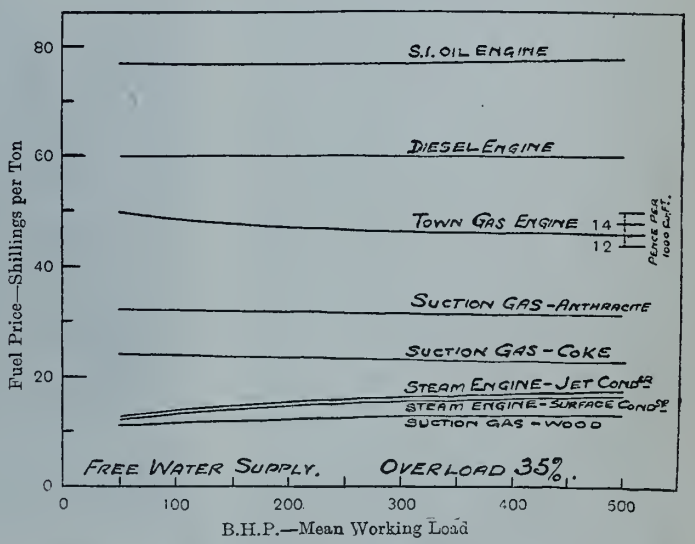

FIG. 8

*Read before the Institution of Mechanical Engineers, London, Oct. 19, 1917.

and handy type of man. Wages at the rate of 6d. per hour have been allowed for in the cost curves, Figs. 5 and 6.

Water Consumptions.

Installations	Surface Condenser Water Gals. per b.h.p.-hour	Jacket Water Gals. per b.h.p.-hour	Piston and Exhaust Valve Gals. per b.h.p.-hour over 100 b.h.p.	Scrubber Water Gals. per b.h.p.-hour	Dust Collector Gals. per b.h.p.-hour	Tar Extractor Gals. per b.h.p.-hour	Steam to Producer Gals. per b.h.p.-hour	Water Lost by A, B, C, D	Water Lost by Cooler Evaporation	Total Water Lost Gals. per Working Load b.h.p.
				A	B	C	D			
Steam engine.....	45-55	..	..	...	..	..	....	....	2¼-2¾	2¼-3¼
S-I Oil Engine.....	....	6	0.5	...	..	..	....	....	0.325	0.325
Diesel Engine.....	....	5	0.5	...	..	..	....	....	0.275	0.275
Gas Engine:—										
Town Gas.....	....	6	1.5	...	..	..	....	....	0.375	0.375
Anthracite and coke	....	6	1.5	1.75	..	..	0.075	1.825	0.375	2.2
Wood, etc.....	....	6	1.5	...	4	1.5	....	5.5	0.375	5.87

The following formulae give a fair indication of the time that is spent solely upon the prime movers within the scope of this paper:—

Suction gas (wood fuel) and steam engine plants .....0.8 + 0.0047 b.h.p.
Suction gas (coal and coke fuel)..0.6 + 0.0041 b.h.p.
S.I. and Diesel engines.....0.3 + 0.0036 b.h.p.

These expressions give the labor in hours per rated working load per hour. Thus for a 100 b.h.p. suction-gas plant using wood fuel, and 100 b.h.p. town-gas engine, the labor would be respectively 1.27 and 0.37 hours per hours run.

Repairs

The annual charge should provide amply for wear and tear and such breakages as are not covered by insurance. The actual annual payment may form an appreciable portion of the running costs, and must in some cases exceed the estimated amount in view of the small provision made. This applies particularly to internal-combustion engines. There is little difficulty in citing instances of gas and oil-engines in which the repair bill over, say, 5 or 6 years, has not exceeded 2 per cent. per annum of the engine cost. Such a figure, however, should not be taken as a basis. If the cost of repairs were entirely dependent upon wear and tear, 2 per cent., there is no doubt, could be taken as a general rate.

Although internal combustion engines have proved themselves to be thoroughly reliable in service, it is nevertheless a fact that they are more prone to minor mishaps than steam engines, and due allowance must be made for a well designed gas or oil-engine, ample margin for this contingency is given by an annual charge of 3 per cent. of the engine cost.

The following are the repair charges allowed for in the Working Cost Curves, Figs. 5-6:—Diesel and S. I. oil engines, town gas engines—3 per cent. of engine cost; suction-gas installations, 3 per cent. of engine and producer costs; steam installations, 2 per cent. of engine, boiler and auxiliary costs.

From the facegoing data it is possible to estimate with reasonable accuracy the annual working costs of the engines under consideration. These costs will be found to differ appreciably with the locality, due mainly to the fluctuations in the prices of water and fuel. The cost of lubricating oil and labor may vary but not sufficiently to affect materially the annual charges. Further, the variation would be common to all installations, so that the relative working costs for practical purposes would be unaltered. The position with regard to the water and fuel supplies however, is quite different. In some districts a free water supply may be available, and in others the charge may be high, whilst the price of fuel, particularly oil, varies considerably from time to time and with the locality, thus rendering these two items almost the ruling factors of economical working.

In order to establish a relationship between the fuel prices that may be paid, and to show the influence of the water charges upon these prices, the curves, Figs. 5 and 6, have been plotted. The curves A to F, 5, give the annual charges with water at 9d. per 1,000 gallons, and in Fig. 6 it is assumed that the water supply is free, but none of these curves include the cost of fuel. The curves G represent the total annual working cost of a Diesel engine using fuel-oil at £3 per ton. It follows, therefore, the total amount that may be spent annually upon fuel to give even running charges for any one of the remaining installations is represented by the length of the ordinate between the curve G, and the cost curve of the particular engine considered. From the total fuel cost thus obtained, the maximum prices that may be paid can be easily computed, and have been plotted in curves Figs. 7 and 8, whilst the fuel prices given by those curves for plants of 250 b.h.p. mean working load are given below:—

	Price of Fuel Curve Fig. 7 per ton	Price Ratio	Price of Fuel Curve Fig. 8 per ton	Price Ratio
Diesel engine.....60/		0.79	60/	0.785
Solid injection oil engine 76/		1.0	76/6	1.0
Suction Gas:—				
Anthracite 29/		0.38	31/6	0.41
Coke 21/		0.27	23/	0.3
Steam Engine:—				
Wood 8/6		0.113	12/	0.157
Jet Condenser		...	16/	0.21
Surface Conden..14/		0.184	15/	0.195
	per 1000 cu. ft.		per 1000 cu. ft.	
Town & gas engine 1/1		0.014	1/1	0.014

In the curves, Figs. 5 to 8, the engine possessing the highest thermal efficiency, namely, the Diesel engine, has been taken as a convenient basis using fuel oil at £3 per ton. Reference to these curves shows that the relative fuel prices for the several installations are fairly uniform for the range of power under consideration. The widest variation is that shown for the steam plants due to the comparatively higher initial cost and lower thermal efficiency of the smaller powered engines. It should be noted that the fuel consumptions represented by the curves, Fig. 2, are favorable to the steam-engine and apply to compound condensing installations using superheated steam, that is to say, they are best practice figures. It may be said with certainty, therefore, that, in general practice consumptions as much as twice those represented are not unusual, thus nearly halving the fuel prices shown by the fuel price curves, Figs. 7 and 8, and further limiting the districts in which the use of the steam-engine can be defended on the score of minimum working costs.

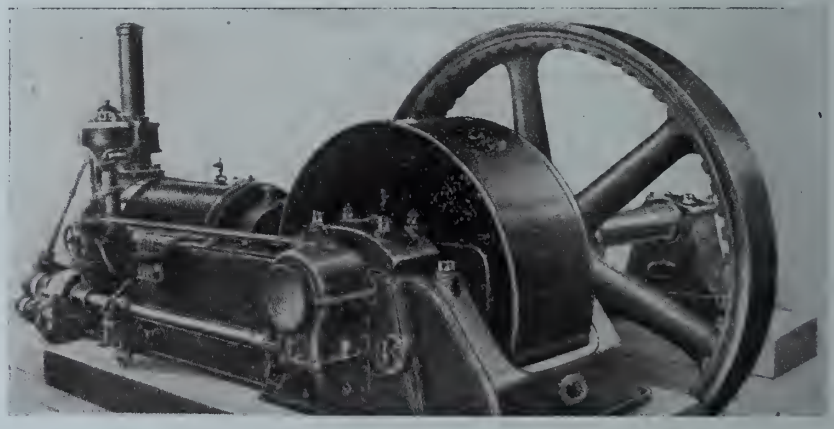

FIG. 9. SOLID-INJECTION HIGH-COMPRESSION OIL ENGINE

As the power increases a higher price may be paid for coal, and the steam-engine becomes a more serious rival of the suction-gas plant; nevertheless, for installations up to 500 b.h.p. working load the latter well holds its own, for it is possible to obtain even running costs with fuel ranging in price, according to the power, from two to three times that permissible for a steam-plant. The price allowable for town-gas is practically constant at 1s. 1d. per thousand

cubic feet, and consequently confines the use of the town-gas engine to cities in which gas is procurable at this low rate.

Calorific Values Assumed		
Anthracite	14,500 B.Th.U. per lb.	
Coal (Boiler)	13,500 "	"
Fuel Oil	18,000 "	"
Wood Refuse	5,800 "	"
Town Gas	540 "	1,000 cub. ft.

Turning now to the high-compression solid injection-oil engine. A high price may be paid for fuel-oil, namely, £3 16s. per ton as compared with £3 for the Diesel engine, or a price some 26 per cent. higher, notwithstanding the higher thermal efficiency of the latter engine. The lower capital expenditure and other running charges of the solid injection-engine are responsible for this result. The future of the oil-engine must be obviously dependent upon a regular supply of uniformly low-priced fuel-oil, and it is to be feared that past irregularities in these respects have to a certain extent militated against their more extended application.

Fuel Supply Problem

The problem of the supply of a uniformly low-priced fuel-oil is one that is well worth the serious consideration of the large oil companies, and it is satisfactory to note that during the twelve months prior to August, 1914, one companying had gone a long way to establish a feeling of security amongst users of oil-engines by offering fuel at an average price of £3 per ton, and were prepared to contract for a regular supply over several years. There seems to be every probability of these conditions again becoming general after the war. An adequate supply of fuel oil, in view of the high thermal efficiency of the oil engine, is of the utmost importance to be followed with advantage in the case of fuel oil.

With the fuel oil at £3 per ton, the price of coal must not exceed on the average £1 5s. and 12s. per ton respectively for suction gas and the larger steam plants over 250 b.h.p. in order that the total annual running charges do not exceed an oil-engine of the solid injection type, clearly indicating the wide field of action of this type of engine. The cheaper grades of fuel oil of not less than 0.95 sp. gravity alone are considered, as the charges of engines using the more costly and refined oils are appreciably higher and therefore commercially inferior. In Fig. 9, page 342, is shown a high-compression oil-engine of the solid-injection type, capable of handling the cheapest fuel-oils with an economy in conformity with the curves, Fig. 2 (page 309).

Considering lastly the refuse suction-gas plant, the price of the fuel ranging as it does from 11s. to 13s. per ton, even with a free water supply, limits its use to industries in which the wood or other refuse mentioned below is a waste product of the industry, for it is seldom possible to obtain a constant supply at these rates. Under this condition refuse installations are unquestionably the cheapest form of power. The illustration, not shown, shows the producer of a 300 b.h.p. suction-gas installation working entirely upon sawdust, shavings, wood blocks, etc. A producer of this type will also handle such refuse fuels as various kinds of husks and nut shells ,bark, spent tan, plum stones, etc.

The use of suction-gas as a heating agent is yet in its infancy, but very satisfactory results have already been obtained in laundries, woodwarking factories, tinsmiths' shops, etc. The gas is drawn from the producer through a purifier and pumped to a gas-holder, from which it is piped under slight pressure to any part of the factory, and by the aid of an air-mixer and burner used in a similar manner to town-gas. This feature is worthy of consideration, for it adds to the general utility of the suction-gas installation, and may in some cases effect an appreciable economy in the working costs. The plant, supplies gas for heating purposes in addition to that required for power. The possibilities of the system suggest many applications in which economies could be effected.

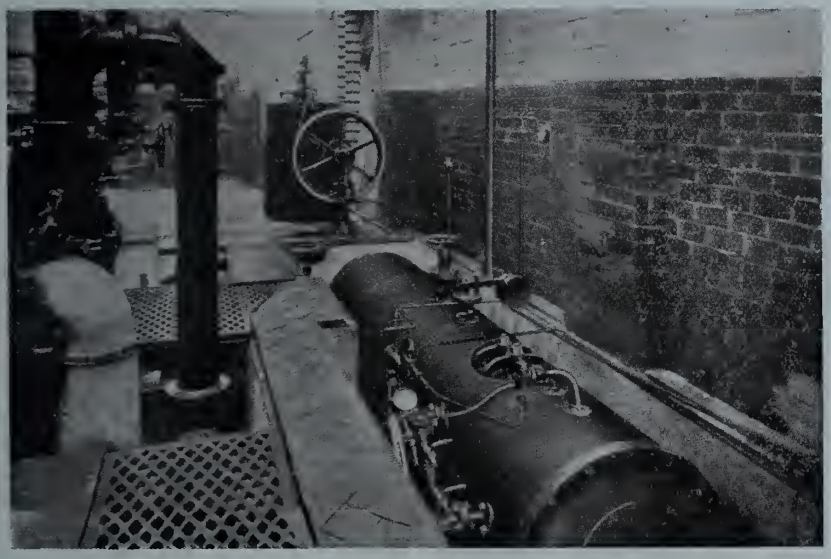

FIG. 10. BOILER HEATED BY EXHAUST FROM 250 BRAKE HORSE-POWER SUCTION-GAS ENGINE

manufacturers, for it offers a means by which minimum working costs may be obtained. It is usual in the supply of electrical and hydraulic energy for power purposes, for the suppliers to charge specially reduced rates, and it is suggested that a similar procedure might

An objection sometimes advanced against the adoption of the internal-combustion engine for certain classes of works as, for example, tanneries, laundries, cotton mills, factory heatings, etc., is its inability to provide a steam-supply. This difficulty has, however, been met to a large extent by the exhaust heated boiler which is capable of supplying about 2 lb. of steam, from and at 212° F. per b.h.p.-hour of the engine. The steam being generated from the exhaust heat that would otherwise be wasted may be truly stated as costing nothing beyond the small additional charges due to depreciation and interest upon capital. The illustration, Fig. 10, herewith shows a boiler working in conjunction with a 250 b.h.p. suction-gas engine, and is capable of supply about 500 lb. of steam per hour, which is equivalent to the saving of 65 lb. of coal per hour.

Conclusion

It is evident from the foregoing that statements to the effect that a certain class of engine is the most economical requires qualification. It has been shown that the cost of fuel has a deciding influence upon the working cost, although that due to the necessary water-supply may be serious in some districts. Now, as the cost of fuel is regulated largely by railway and shipping freights, it is clear that the distance from the source of supply has an important bearing upon the kind of fuel, and it follows the type of engine that should be installed.

The maximum permissible prices that may be paid in any locality are indicated generally by the ratios given, and more particularly by the curves, Figs. 7 and 8 page 341. The practical application of these price ratios shows that each type of engine has its particular field of action in which it can be used with commercial advantage, provided due regard is paid to the local conditions, or in other words, an exclusive claim to minimum working costs cannot be rightly made on behalf of any one of the prime movers under consideration.

The relative fuel prices do, however, indicate that the scope of the steam-engine is less than the oil-engine, for in the best practice of the former the price of coal for the larger installations of 250 h.p. and upwards may not exceed on the average one-fifth of the price of fuel-oil for an engine of the solid injection type and one-fourth for Diesel engines, and appreciably less for smaller powers. Between these extremes stands the suction-gas plant, for which the price of coal and coke may be respectively twice and 1½

times the price of coal for steam-engines of the larger powers. The use of town-gas engines is clearly confined to the few cities in which gas can be obtained at about 1s. 1d. per 1,000 cubic feet, and the refuse suction-gas installations to industries in which there is an ample supply of suitable waste material.

It is obvious, therefore, that the commercial superiority of a prime mover is not established by reference to its thermal efficiency, but by the local conditions regulating the price of fuel. From the purely engineering point of view this is not entirely satisfactory in that, however thermally efficient an engine may be, the ultimate test is a commercial one involving the market price of fuel, which must always depend upon the facilities for distribution from the source of supply. In practice, therefore, railway and shipping freights have a marked and direct influence upon the type of engine giving the most favorable performance from the commercial standpoint.

The whole problem is one that cannot but force itself more and more upon manufacturers with the keener competition that may be expected in the near future, and unless correctly solved must tend to handicap any industrial concern as the result of the higher establishment charges that must necessarily follow. The right solution not only benefits the manufacturer, but also affects an economy in the national resources by preventing the waste of fuel so frequently met with in practice, suggesting that minimum costs are either not sought or that the regulating conditions are not fully appreciated by those responsible.

BEFORE AND AFTER

By N. G. Near.

THE accompanying photographs show how modern equipment is doing away with the dust nuisance in industrial establishments. Fig. 1 shows how ashes

FIG. 1. BEFORE.

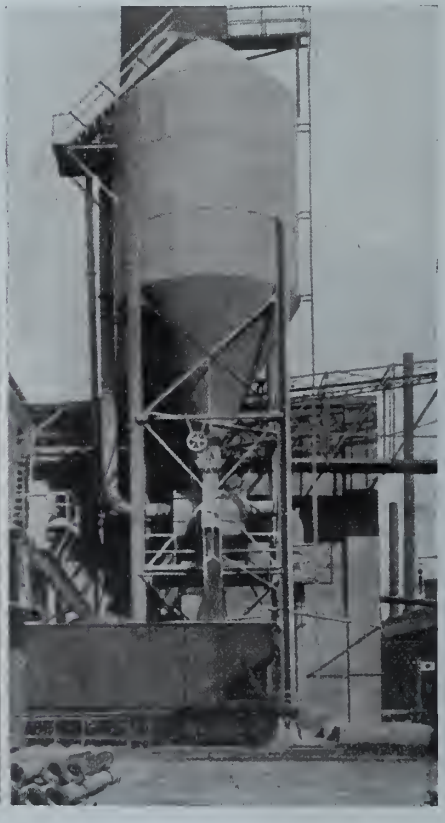

FIG. 2. AFTER.

were once loaded into a car by means of a clap-trap belt and bucket arrangement. It was often unendurable for the men to work in the vicinity of this loading machine under certain conditions—when the wind was just right and when it was real hot. This view was taken while the steel structure shown in Fig. 2 was being erected. The bottom of this steel structure is visible in Fig. 1.

Fig. 2 shows how the ashes are loaded now. There is not a bit of dust, because the ashes are well wetted down by simply turning the valve of a pipe line. The ashes are sucked into the tank in the same way that a vacuum cleaner works, and we all know how dustless vacuum cleaners are. The advance in efficiency is sufficiently obvious to render further comment needless.

RECENT DEVELOPMENTS IN POTASH PRODUCTION

THE influence which it is possible for the cement and iron industries to exert on the production of potash is of considerable importance at this time, and the possibility of this influence increasing in the future is the belief of Richard K. Meade, expressed in an article in the "Manufacturers' Record." The necessity for development work on this continent has been growing more urgent with the continuance of the war, some idea of the urgency being conveyed by the statement that the imports of pure potash from Germany before the war amounted to 250,000 tons, while 10,000 tons only were produced in the United States last year, as estimated by the Geological Survey.

Recent reports in Canada indicated the probability of production being increased by suitable treatment of feldspar in connection with cement manufacture. It seems, however, that the loss of potash by volatilization from rotary cement kilns was pointed out as far back as 1903, and that from blast furnaces still earlier, but before 1914 nothing was done to collect the substance from either source.

Some ten years ago a dispute arose between the orange growers in South California and the cement mills over the question of the damage caused by the dust from the mills being deposited on the fruit trees, and to settle the matter the Riverside Portland Cement Company installed a process for precipitating the dust by the Cottrell electrical system. This process not only proved efficient as a dust-catching device, but also collected the potash with the dust. Most of the potash being water-soluble, it can be dissolved out of the dust by leaching with water. Before the war the raw materials used at Riverside were low in potash, and hence the amount volatilized was small, but after the outbreak of war the company found they could increase the output of potash from their kilns by the aid of feldspar, which can be used without injury to the cement. They also found that mixing fluorspar with the raw materials increased the amount of potash volatilized to 90 per cent. of the amount contained in the raw materials, as against 50 per cent. volatilized under usual conditions. They next extracted the potash from the dust, and by crystallization obtained a potash salt containing at least 35 per cent. of potash. The crust which collects in the stacks of the rotary cement kilns contains from 6 to 12 per cent. of potash, and of this large quantities have been sold to the fertilizer companies since 1914.

In the summer of last year the Security Cement and Lime Company put the Cottrell process into operation in order to catch all their kiln dust. They found that the addition of salt to their raw materials increased the yield of potash, and at present they are obtaining about 20 tons of dust a day, averaging 10 per cent. of water-soluble potash. The Santa Cruz Portland Cement Company are recovering 700 lb. of potash daily from their kilns by a process of their own, and a number of other cement companies are installing or have installed Cottrell plant. When all these plants are in operation Mr. Meade estimates that they will yield about 10,000 tons of potash annually, and this amount, he states, could be very greatly increased by using feldspar as a raw material.

As to potash from blast furnaces, the only iron company in America, so far as he is aware, selling potash at present is the Bethlehem Steel Company. Up to the present only the dust which can be collected by means already at hand has been sold, the amount being estimated at about 4 per cent. of the total potash liberated; but the chemist of the company believes that apparatus could easily be installed to catch at least 50 per cent. of the potash now lost, and that the apparatus, so far from interfering with the operation of the plant, would benefit it through the better cleaning of the gas for the engines. It is estimated that of the potash volatilized in the blast furnaces the amount recoverable will average at least 10 lb. per ton of pig iron,

so that with an annual production of 25,000,000 tons of pig iron the blast furnaces of the United States would produce, say, 125,000 tons of potash.

PECULIAR RESULT OF COLLISION BETWEEN TWO TRACTORS.

AN UNUSUAL ACCIDENT

By A. L. Loy.

THE plant manufacturing the four-wheel-drive tractor shown in the accompanying photo was located quite close to a medium-sized river, which was in the habit of overflowing its banks quite often, and when this occurred it was necessary to move everything possible to a safe distance. In one instance the river came up rather suddenly and it was necessary to run to a safe distance quite a number of these tractors.

The tractor at the right had been run safely up on the side of a small hill and left there, while the operator went for another. In backing up the second tractor, he either became confused, as might be expected in such a case, or else failed to see it entirely. In either case the tractor was coming at full speed, and when the rear driver struck the stationary tractor it simply climbed right up the front end, and when stopped the wheel and, consequently, the greater portion of the weight of that end, was hanging on a five-eighths inch nut on the front end of the frame.

When the collision occurred the operator had presence of mind enough to pull out the clutch before he was thrown off the outfit to the one side. The first tractor was uninjured in any way, although the lugs on the wheel were within a fraction of an inch of the radiator. Practically the only damage done to the moving tractor was the breaking of a ball-and-socket joint over the front axle. The machines steered from both axles as well as having the power applied to all four wheels. The state of the ground through which the tractors had been moved may be judged from the condition of the wheels.

NEW CENTRIFUGAL PUMPING PLANT AT TORONTO RIVERDALE STATION

THE motor driven centrifugal pumping plant recently completed at the Riverdale Station of the Corporation of Toronto is of interest to municipal and other engineers, owing to the great flexibility of speed and capacity of the unit. It was designed to deliver five million imperial gallons in twenty-four hours against a head of 170 ft. and running at a speed of 720 revs. per min., but owing to probable variation in pressure and capacity the city required the unit to deliver either three million gallons or one million gallons against a lower head varying from 130 ft. down to 70 ft.

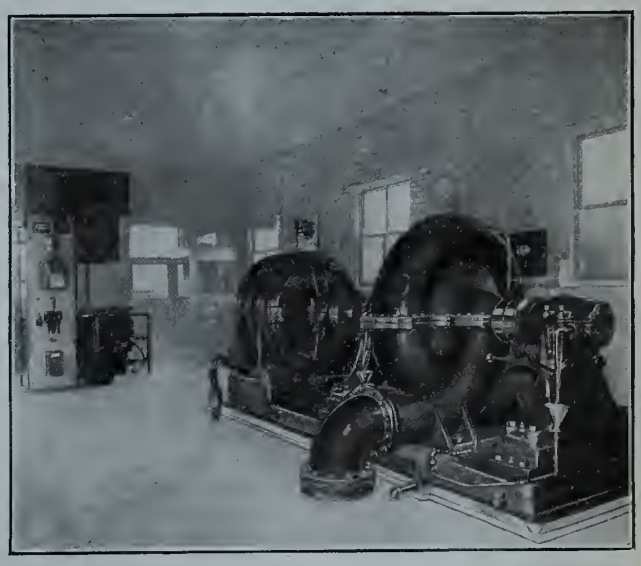
Under such conditions, it is usual to build a multi-stage pump but the contractors, Canadian Allis-Chalmers, Limited, designed and built a single-stage pump which has fulfilled all the guarantees required by the city. The usual practice also is to supply constant speed induction motors for centrifugal pumps; however, as the speed to fill the above requirements must vary from 720 revs. per min. down to 350 revs. per min., the Canadian General Electric Co. built a special 250 horse-power variable speed motor which also fulfills all the requirements.

The pump, which is single-stage with split casing, consists of a cast iron spiral casing with discharge and suction inlet cast on to the lower body. The casing is split on a horizontal centre line, so as to facilitate inspection without dismantling pipe or any other part of the unit. A set of removable diffusion guide vanes has been provided so as to guide the water from the impeller to the casing in the most effective manner. The impeller is made of cast bronze, and polished so as to eliminate unnecessary friction.

Special neck rings have been provided so as to decrease the water leakage from the pressure side to the suction side. The impeller is of double suction type and the head of 170 ft. is generated in a single stage. Proper stuffing boxes are arranged on each side of the extending shaft, and bronze sleeves are provided to eliminate rust and prevent undue wearing. The shaft itself is of hammered steel and of ample stiffness to prevent any vibration.

Separate outboard pedestal bearings are provided in order to carry the shaft, and one of these bearings is arranged with forged collars which act as a thrust bearing to take any unbalanced thrust which might occur occasionally. All bearings are arranged for water cooling, and are of the self-aligning ring oiling type. Separate sub-bases are provided to facilitate dismantling and direction. Both bearings are tied up to the main pump casing by means of stay bolts, so as to make the whole unit as rigid as possible. A flexible pin type coupling is arranged for connecting up this pump with the motor.

The whole unit is set upon a heavy cast iron base-plate which is grouted in to the foundation, and has proven to be exceedingly quiet during operation. An efficiency of well over 70 per cent. has been shown operating under various conditions.



CENTRIFUGAL PUMP WITH CAPACITY OF 5,000,000 IMPERIAL GALLONS IN 24 HOURS.

Big Harbors Needed When War Over.—Improvement in sea transportation was discussed at the London, England, Chamber of Commerce, on Dec. 5, when Lord d'Abernon emphasized the need of bigger ships of great speed after the war. He suggested the government should start the provision of big harbors. About $20,000,000 would provide for vessels of 38-foot draught at practically all the leading harbors from Great Britain to the furthest dominion. The report of the Dominion Royal Commission just issued gives memoranda and tables as to harbors throughout the Empire.

Steam and Its Generation

STEAM POWER DEVELOPMENT*

A SHORT time ago V. H. Manning, Director of the Bureau of Mines, Department of the Interior, Washington, D.C., made the statement that 25 per cent. of the coal production of the United States was wasted through inefficient use. His point was that a large proportion of the steam engine and boiler plants of the country are not up-to-date and are consuming coal wastefully as compared with results given by plants of the latest and most approved design.

Since engineering methods are always advancing, it is out of the question that all of the power plants of the country should be at any one time of the latest design, but Mr. Manning's statement is very suggestive as to the importance to the country of improvements in its power equipment. The annual production of coal in the United States is now about 600,000,000 tons, and 150,000,000 tons of this would be saved if all consuming plants were as good as those of the best type. Perhaps the most impressive idea of this saving can be obtained if the reader will think of the labor involved in mining, handling, and transporting 150,000,000 tons of coal, and of shoveling it into the fire-boxes; and of the benefits that might be derived by having that labor distributed in the other industries.

Generation Back Comparison

If it is interesting to calculate the savings that may be effected in the future by bringing all equipment up to the standard of what at this date is recognized as the best, it is also interesting to compare not only the best practice but the common practice of to-day with the best practice of a generation ago. Mr. Manning's statement has led us to make an inquiry along this line, says a statement issued by the National City Bank, New York, and looking backward for a starting point we fixed upon the Centennial Exhibition at Philadelphia in 1876. Doubtless many of our mature readers will remember viewing, as youths, with awe and wonderment, the great Corliss engine which stood at the centre of Machinery Hall, and furnished the driving power for all the exhibits in the building. There were seats for the public about the engines; the motion of the great flywheels created a breeze, and the engine was the admiration not only of the non-technical public, but of the members of the engineering profession from all over the world.

With the Corliss engine standing out prominently as a landmark in engine development, we appealed to President Alexander C. Humphreys, of Stevens Institute of Technology, for information as to progress in engine-building since that time. It will add a touch of human interest to the story to state that it then developed that Professor Robert M. Anderson, of the Department of Engineering, Stevens Institute, was in part influenced to his choice of a profession by seeing, as a boy, the big Corliss engine in Machinery Hall. By the courtesy of Stevens Institute we have the interesting sketch which follows:

To summarize in the briefest possible manner the progress which it records, the Corliss engine at the Centennial occupied about 54,000 cubic feet of space and consumed 2.2 pounds of coal to develop one horse-power; while a modern steam turbine of equal capacity will occupy 115 cubic feet of space and consume nine-tenths of a pound of coal to develop a horse-power, giving a saving in coal consumption of 59 per cent. According to Mr. Manning's estimate, that the average engine efficiency at the present time is 25 per cent. below the standard of the best type, the average now is well above the best of 1876; and, of course, the average efficiency in 1876 was much below the Corliss standard.

Electric Power Transmission

Even more notable than the improvement in engine and boiler efficiency is the gain accomplished by the development of power transmission through the electric current. The transmission of power by electricity was unknown when the Centennial Exhibition was held, but in the year 1915 51 per cent. of all the power applied to industry in the United States, outside of transportation, was delivered by electric current, and as a result of all this development the total horse-power in use in the United States, to each million inhabitants, was 482,392 in 1915, as compared with 68,182 in 1879, or an increase of more than seven-fold. The facility with which power can be transmitted by electric current does away with the necessity of generating power where it is to be used. It can be generated at the most economical spot, as at the mouth of a coal mine or the site of a water-fall, and the industries which use it may be located in a spot more suitable to them.

High Speed Reciprocating Engines

The introduction of the high speed reciprocating engine dates from shortly after Mr. Edison's invention of the incandescent lamp and development of the direct-current generator in 1881. The isolated lighting plants, followed by small lighting and power plants, gave an impetus to shaft-governed automatic cut-off engines, allowing of higher rotative speeds than were attainable with drop cut-off mechanisms. Among these were: the Buckeye, the Porter-Allen, the Fitchburg, the Armington and Sims, the McIntosh and Seymour, the Ball, the Westinghouse, the Willans, and many others. These were built simple and compound and were operated either non-condensing or condensing. They varied in economy from 3.6 lbs. of coal per hour per B.H.P. for simple non-condensing to 2.15 lbs. of coal per hour per B.H.P. in compound condensing types.

Up to date the highest economy developed in reciprocating engines has been attained in the Stumpf (Straight) or Uniflow engine, obtaining a B.H.P. on 1.08 lbs. of coal per hour, same being in a 300 h.p. engine with an initial steam pressure of 130 lbs. per square inch absolute, and superheat of 261 deg. F. This record has been equalled by the best performances of stationary triple-expansion engines using steam at 170 lbs. per sq. in. absolute and 203 deg. F. superheat. The highest of all steam engine efficiencies so far reached has been obtained by the Wolf tandem-compound "locomobile," which consists of an internally fired through-tube boiler, having the engine combined so that the cylinders are jacketed by the final pass of the hot gases flowing to the stack—in other words, the cylinder projects into the smoke box. The initial steam pressure is from 175 to 225 lbs. per sq. in. absolute, is superheated to 800-850 deg. F. before entering the high pressure cylinder and again superheated to 450-500 deg. F. before entering the low pressure cylinder. The feed water is heated in an economizer in the breeching. The coal consumption of 1 lb. per hour per B.H.P. is common practice and 0.8 lb. per hour per B.H.P. has been attained.

The Steam Turbine

The reaction type of steam turbine, known under his name, was first introduced in England by the Hon. Charles A. Parsons in 1884, and was introduced in the United States by the Westinghouse Co. in 1895, but it was not until about 1900 that it met with general approval. The DeLaval impulse turbine was introduced in its present form in 1889. The compound velocity impulse turbine, known as the Curtis, was introduced into the United States by Charles G. Curtis about 1896.

Since their introduction there have

been many modifications and combinations of these types, better fitting their application to various power developments. For central station work the steam turbine has replaced the reciprocating engine. In fact, the turbine has the advantage in all electric generation, especially in the larger outputs. This is not, however, on account of better fuel economy, since for the same grades of machinery and equal ranges of temperature, pressure, etc., there has been found no appreciable difference in economy betwewen the best turbines and the best reciprocating engines, other characteristics influencing the preference. The real reason for the replacement of the engine by the turbine has been the greater compactness of the latter, thus resulting in a smaller investment in real estate.

Boiler Efficiency

There has been marked improvement in boiler efficiency since 1876. The combined efficiency of furnace and boiler, being the ratio of delivered energy in the steam to that available in the fuel, ranges in coal-fired boilers from about 55 per cent. to 75 per cent. With liquid (oil) fuel and powdered coal, 80 per cent. is attainable. The most remarkable and promising development, the restriction being that the fuel must first be transformed into a gas, is the Bone system of so-called "surface combustion." This consists in burning a perfect mixture of gas and air in boiler tubes filled with porous refractory material, the result being incandescent combination, with no radiation or excess air losses. An efficiency of 94 per cent. has been attained.

Service of Capital

The development of the steam engine illustrates very clearly the part which capital plays in community progress. A steam engine is the servant of the community, no matter who owns it, and the improvements upon the engine, the changing over of power plants to bring them up-to-date, and the construction of new power plants, constantly absorb an enormous amount of new capital. Into such enterprises the profits of business largely go, while the resulting benefits go to the entire community. The man without property, who spends every dollar of his income the same week he receives it, is able to buy more with his wages, because steam engine efficiency has been doubled in the last forty years.

Making Good War Losses

The world is suffering frightful losses through the war, and people are wondering what the effects of these gigantic debts will be upon the earnings of industry and the welfare of the peoples. We may learn something about this from the experience of the past. "It is our improved steam engine," wrote Francis Jeffrey in the "Edinburgh Review" in 1819, "that has fought the battles of Europe, and exalted and sustained, through the late tremendous contest, the political greatness of our land. It is the same great power which enables us now to pay the interest on our debt and to maintain the arduous struggle in which we are still engaged with the skill and enterprise of other countries less oppressed with taxation."

The steam engine which helped England bear the burdens of the wars with Napoleon was a poor affair compared with the engine of to-day, but even the latter, as Mr. Manning and Professor Anderson have indicated, may have its average efficiency in practice greatly increased. Beyond these prospective gains are those which lie in other sources of power, and in all the improvements in industrial equipment which are only partially introduced, or as yet only forming in the minds of inventors. More important than all these are the possibilities which lie in more thoroughly organized and harmonious industry, the development of intelligence and efficiency among the people, and the spread of a better understanding of common interests. We must look to these changes for gains in production which will enable society to overcome the losses of the war, and repeat the progress accomplished by the original application of the steam engine to industry.

THE FIRST HEINE BOILER

AFTER a fire which destroyed the National Guard Armory in St. Louis, Mo., a few months ago, the Heine Safety Boiler Co., of that city, obtained possession of the first Heine boiler ever built, which was installed at the armory in 1881. It has 24 tubes about 10 ft. long; the heating surface is approximately 250 sq. ft., making the rating of the unit 25 h.p. The boiler was built in the shop of Richard Garstang, St. Louis. The original pressure for which it was designed was about 100 lbs. and an inspection certificate from the Fidelity & Casualty Co. has been received to the effect that they will certify this boiler to carry 80 lbs. pressure at the present time.

This indicates a somewhat longer life for water-tube boilers than is usually credited them by accountants or engineers when apportioning depreciation charges. However, under modern conditions the heavier loads on boilers would perhaps tend to lessen their life as compared to this little boiler. One odd feature is the casting which forms both the steam outlet and the water column. Another obsolete feature of this boiler is the vertical baffling which was discarded in later designs for the horizontal baffling, now the standard with Heine boilers of both the land and marine types.

GAS VERSUS STEAM POWER

THE gas engineer changes coal into coke, gas, etc., which afterwards produce heat by combustion. The heat produced by their combustion may be taken as 75 per cent. of the original heat in the coal, but for this efficiency no power whatever is produced. The gas engineer has only changed one source of heat for another source of heat. On the other hand, the steam engineer produces power from the coal; that is, he changes heat into work which is quite a different proposition from merely changing one source of heat into another source of heat.

When the gas engineer has also turned his heat into work he will find that only about 20 per cent. of the heat in the coal has been turned into useful work. The comparison therefore is that a gas engineer producing power from coal will convert about 20 per cent. of the heat of the coal into useful work in a good gas engine, whereas a small steam engine will convert 7½ per cent. of the heat into useful work. Large modern steam turbines are now converting from 16 to 20 per cent. of the heat in the coal into useful work, and thus compare very favorably with gas engines. In addition, steam turbines have been built in single units up to 50,000 kilowatts, are cheaper in first cost and in cost of maintenance, being thus in general more suitable for central power plants.—J. W. Kershaw.

EFFORT TO CONSERVE FUEL SUPPLY

THE U.S. Fuel Administration is making an energetic effort not only to stop the waste of coal but to limit its use as nearly to necessary purposes as the conditions of supply require. A great deal of coal is used for purposes that can be easily dispensed with, even where there is not actual waste.

The official directions sent out to practically all the producers in the East and Middle West require preference to be given to the Government orders, railway fuel, household needs, public utilities, steel plants, coke ovens and munition plants, in that order.

The assumption seems to be that all of these may be adequately supplied if preference can be given to them in deliveries. Their importance is obvious enough, though in the case of household requirements many exceed what is really necessary for health and comfort.

One of the savings proposed is to be effected by the conservation of electric power, which is developed by a large consumption of coal. Among other things it is proposed that railroads which use that power, as most local and short lines do, shall limit their schedules and dispense with extra cars as far as feasible. It is also proposed that they use in cars less heat and light derived from electricity, which is generated by consuming coal. This is likely to be acceptable to operating companies as it will reduce their expense, but it rather comes in conflict with some demands, not only of those using the facilities but of local authorities.

Within that same period of memory not so very long, there was no electric light at all. Now it is squandered on a huge scale in cities, not in a comfortable degree of lighting merely, but in extravagant illumination of many kinds, kept up the greater part of long winter nights.

Electricity and Hydraulics

EXCESS ELECTRIC POWER CONVERTED INTO STEAM

A TYPE of electric steam generator which for some years past has been in use in large numbers in many Italian works is illustrated in Figs. 1 to 5. The apparatus according to "Engineering," to which we are indebted for the illustration, is an invention of Engineer Revel, Colonel in the Italian Army, the manufacturing rights being held by Messrs. Luigi Boselli & Co., Milan.

The principle on which it works is the evaporation of water into steam by means of the heat dissipated in overcoming the resistance of the water to the passage of an electric current. As the flow of current depends on, and varies directly as, the volume of contained water acting as a conducting medium, the control is entirely automatic and demands no attention. Thus lack of feed water would only result in a decrease or stoppage in the production of steam until the supply of water to the boiler was resumed. An efficiency as high as 98 per cent. is characteristic of this type of boiler since the whole of the heat generated by the electrical energy is absorbed by the water, the only loss being that caused by radiation from the body of the apparatus.

Alternating current of from 200 volts to 3,600 volts may be applied, the only difference between the high tension type and the low tension type being a modification in the shape of the electrodes and the dimensions of the steam dome. Fig. 5 illustrates the half of an installation of eight units taking three phase current at 6,000 volts, each apparatus being capable of generating 405 pounds to 450 pounds of steam per hour.

Figs. 1 to 4 illustrate a similar apparatus designed for 500 volts, the arrangement of the component parts being clear from the explanatory notes accompanying the illustration. For starting the generator the circuit-breaker is closed, the valve i is opened, and a small quantity of soda solution is introduced from the small receiver e to give a suitable conductivity to the water. When the water has reached the height of the lower edge of the electrodes the current flows through the water and commences to raise steam, the steam production increasing as the water-level rises, until it reaches the working pressure required. At this moment the regulator f enters into action, and the water-level and hence the steam production remain constant. In order to stop the apparatus the feed-water valve i is closed, the steam valve b is closed slowly, and the drain valve g is opened by acting upon the hand lever h until the ammeter has returned to zero.

When the feed water leaves a calcareous deposit it is advisable, every five or six hours, to free the boiler of the sediment deposited at the bottom of the truncated cone. This is obtained, without interrupting the working of the machine, by increasing the water feed and by acting at the same time on the handle h, the excess water washing away the sediment; this operation, by a suitable action upon the valves i and g, and by following closely the ammeter and maintaining the current intensity constant, is carried out without changing the water-level and without impairing the working of the apparatus.

The Revel generators are constructed to work at any pressure up to 14 atmospheres, and can be connected up at any time with the steam pipes from the ordinary steam boilers; owing to the rapidity of their action they take up any excess of hydro-electric energy which may be available even for a short time. They may, in fact, be considered as serviceable appliances for turning to account any superfluous hydro-electric

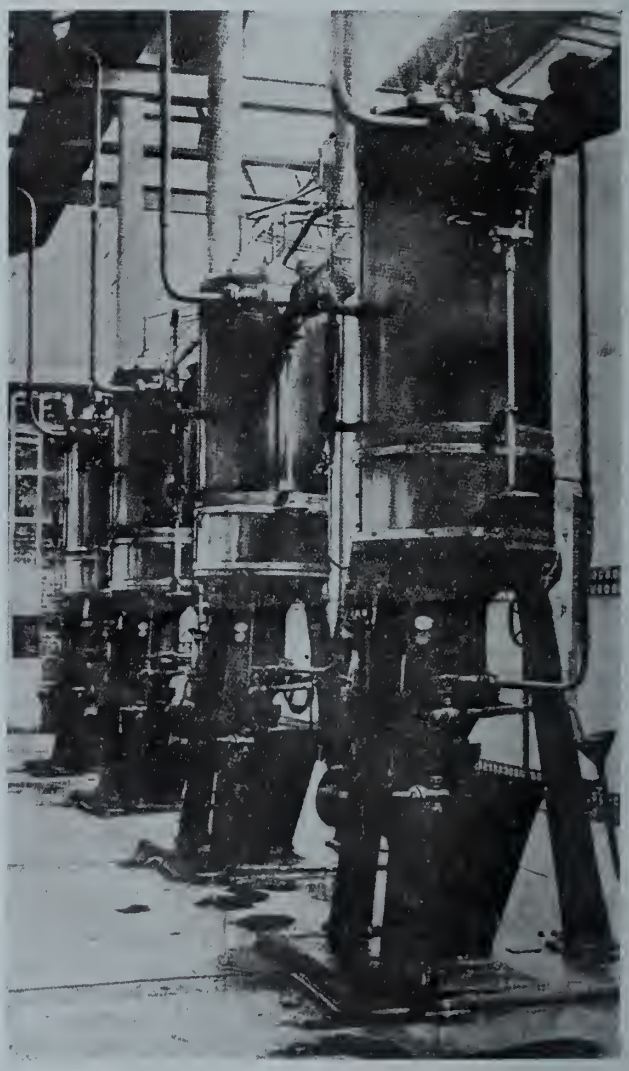


FIG. 5. EXTERIOR VIEW OF BATTERY OF ELECTRIC STEAM GENERATORS

power available, and as such they were utilized in numerous installations in Italy before the war, when the price of coal did not exceed 32s. per ton. At the present time they are also found to be practical and economical, even in cases where hydro-electrical power has to be paid for at the rates now ruling.

ELECTRICAL NOTES

Power Factor of Induction Motor.—Does the power factor of an induction motor change with the load, and how can it be measured? J. S.

Answer.—The power factor of an induction motor is greatest at full load, and decreases on light loads and overloads. Power factor meters are supplied for measuring this factor, but a substitute method may be used when a wattmeter, voltmeter, and ammeter, of the correct capacity and range are available. Connect the wattmeter series coil in one phase of the motor with its potential coil terminals across the phase to measure the watts imput per phase. Also measure the volts and ampere imput for the same phase. Then the power factor is the true power consumed in watts divided by the total power imput in volt $\times$ ampere $=$ w. / v. $\times$ k.w. / k.v.a. J. S.

* * *

Size of Wire.—Can you state what size wire I should use to connect a 7 h.p., 550-volt direct-current motor to the switchboard in the engine room, located about 750 ft. away from the motor? N. McC.

Answer.—The difference in potential at the beginning end end of the circuit you propose to instal, or in other words, the line loss, will govern the size of wire used to carry the load. The allowable line loss for the motor may run as high as 10 per cent., the object being to use the least possible copper consistent with economy and safety. We will assume in this case the line loss to be 5 per cent. and the efficiency of the motor 90 per cent. Then the volts lost in the line will be $\frac{5}{100} \times 550 = 27.5$ volts and the voltage impressed on the motor will be $550 - 27.5 = 522.5$ volts.

The watts taken from the line by the motor are $\frac{\text{H.P.} \times 746}{\%\ \text{Efficiency}} = \frac{7 \times 746 \times 100}{90} = 5{,}800$ watts.

Gives $\frac{5800}{522.5} = 11.1$ amps. taken by motor.

We have then the current flowing in the wire to be 11.1 amperes and the voltage drop in the line to be 27.5 volts. The resistance, then, is given by the formula $C = \frac{E}{R}$ $R = \frac{E}{C}$;

$$\text{Resistance} = \frac{27.5}{11.1} = 2.48 \text{ ohms.}$$

This is for a length of wire $= 750 \times 2 = 1{,}500$ ft., for it is a two-wire circuit.

The wire tables found in any mechanical handbook give the size of wire in B. & S. gauge opposite values of resistance in ohms per 1,000 ft. In this case the resistance in ohms per 1,000 ft. $= \frac{2.48 \times 1000}{1500} = 1.65$ ohms, and comes between the values 1.58 for No. 12 wire and 2.00 for No. 13. The even gauge numbers are most usually used commercially, so choose the next smallest size, No. 14, as being the most economical of copper, if no mechanical strain is placed upon it. If, however, it is to be run out of doors on insulators, the use of No. 12 would be preferable as being mechanically stronger.

A, electrode and steam space; B, cold water space; C, cover (steam dome), through which run three brass rods a electrically insulated from the cover; D, steel electrodes rigidly fixed to the rods, a; E, steam pipe; F, steam pipe support and baffle: G, feed-water injector; b, steam valve; c, water gauge; d, pressure gauge; e, receiver for soda solution; f, water-level regulator, which automatically governs the working of the apparatus; g, safety and drain valve; h, handle for working valve g by hand; i, feed-water valve.

Modern Steam Power Plant and Its Appliances-II.

By John H. Hale*

Despite the wonderful developments of hydro-electric power generation, the modern steam power plant occupies a firmly established position in engineering effort from which its removal, if it take place at all, will never be more than temporary. The economies possible in large plants and the duty of all engineers to adapt such methods to their small individual plants wherever possible is emphasized by the writer.

THE subject of furnace efficiency is one which may be expanded almost indefinitely, and involves a consideration of all the requirements of modern stoking and the inability of the individual to divide his attention and obtain the same result as when his attention is concentrated. In other words, it involves not only the preliminary of machine efficiency, but involves the question of human reliability and human weakness. I desire, therefore, to set forth the relation between furnace efficiency and the usual practice in boiler room management.

Efficiency and Practice

It is a well known fact, and one from which the plant owner continually suffers, that it is extremely difficult to get the same efficiency from a number of units in service simultaneously that may be developed when one unit is under test. The engineer in charge will usually proceed by taking some one unit and fitting it with the necessary pump and measuring apparatus for conducting a boiler trial or test. He will find, perhaps, that his furnace is not developing the efficiency to be expected.

The results of his preliminary run will indicate perhaps too high a percentage of free oxygen in the gases, too large an amount of CO, or too high a temperature of flue gases. The next step will be to remodel the furnace, change the type of grate surface, add to his height of chimney, increase his combustion arches, or in other ways seek to provide more satisfactory conditions for the development of those results which he knows he requires. Herein lies the first test of the engineer's ability, and no one can prescribe more than general rules for the perfecting of his boiler units. A reiteration of the essentials for furnace efficiency need not now be set forth in detail, as they are common property and have been rehearsed so often that they are practically universally known. The exact means, however, that must be used to secure the desired result is an entirely different problem, although if the engineeer has the ability to properly measure and co-ordinate the existing conditions, the remedies are usually comparatively obvious.

The problem of putting into practice the remedies which he knows are necessary is another difficulty. The area designated as head room and floor space is to hold therein the products of combustion until such combustion is complete, and to support the burning fuel in such a manner that it may be burned with the minimum practicable amount of air.

Commercial considerations render it impracticable to provide a furnace theoretically perfect, as the questions of cost and maintenance are quite as important in the final estimate as questions of daily efficiency, and we continually sacrifice efficiency in the furnace to the initial consideration of original cost, maintenance, depreciation, charges, rent, etc., etc. We have, therefore, to consider a certain efficiency as the maximum efficiency that may commercially be obtained, and this is expressed in terms of the furnace substantially as follows:

1. It is not possible to burn bituminous coal with much less than 50 per cent. excess of air, or in the neighborhood of 18 lbs. of air per pound of coal.

2. It is not commercially possible to burn more than 98 per cent. of bituminous coal fed to the furnace.

3. It is not commercially possible to extract so much heat from the escaping gases that their temperature shall be less than the temperature of the steam at the given boiler pressure.

Primary Considerations

These three primary considerations are the ones which should be first taken into account by the engineer in his analysis of furnace efficiency. The exact methods to be employed by him in determining the means for accomplishing the desired results cannot be herein prescribed, as they differ with every design of boiler furnace and grate surface. That different boilers have different heat absorbing powers is unquestioned, and that different grate surfaces have different capabilities of retaining fuel under combustion is also unquestioned; and that there are different capacities for holding the gases of combustion is perhaps the most obvious of all. It should, however, be the aim of the engineer to secure not less than 10 per cent. of CO in flue gases, which may be accomplished by stopping all air leaks around the setting of the grate surface, by keeping a uniform fuel bed without holes or leaks, by carrying a fuel bed of sufficient thickness that extreme porosity is avoided, and by not opening the furnace doors more than the necessary minimum.

If all the air entering the furnace is compelled to pass through the bed of burning coal or fuel in order to enter the furnace, satisfactory results must almost necessarily follow. It is the unauthorized air leaks that do the damage, and these must be eliminated. All the heat carried away in the escaping gases is lost, and it is obvious that this amount must be reduced to a minimum. Economizers will actually economize, provided the resistance to the flow of the gases offered throughout does not cause greater loss by causing decreased efficiency in the furnace and increased waste in the ash pit. Not only must the temperature of the escaping gases be considered, but adequate furnace draught must be attained or you will lose from the one more than you will gain from the other.

As a general rule with bituminous coal satisfactory combustion cannot take place and proceed with less than .25 in. draught in the furnace. This is without reference to boiler capacity, which is a function of the grate area as well as of the draught intensity.

Flue Gas Temperature

Flue gases in temperature cannot be reduced below 425 deg. F., and a working temperature of 500 to 550 deg. F. is usually considered as satisfactory as it is practicable to obtain. Any increase of this temperature may mean either a short-circuiting of the gases in the boiler, due to defective baffles, excessive velocity of gases in the boiler setting, or air leakage at or near the furnace. It may be due also to defective heat absorbing power of the boiler, the result of scale or soot inside or outside of the tubes. It is safe to say, therefore, that any temperature over 500 deg. in the flue should at once cause an investigation that the absorption may be increased and the waste at this point decreased.

With the unit in a satisfactory condition of efficiency, the next problem is to extend this efficiency throughout the boiler room, and operate a number of units in such a manner that the over all results may be, as nearly as possible, equal to the unit results. This is a question which involves the ability of the operator to divide his attention, and is very largely a question of discipline in the boiler room. It frequently happens, that there is 10 per cent. or 15 per cent. less efficiency, when the entire plant is considered, than is shown in a single boiler test, so it becomes very important that the management should establish such routine and system as will offset the negligence, carelessness, or inability of the fireman.

Systematic Analysis

Perhaps the most satisfactory method is the method of continuous test, which is one of original equipment and systematic operation. In this system each furnace is supplied with coal which passes through a weighing tank, so that the exact amount of coal burned in every furnace is made a matter of

*Executive Secretary, Canadian Association of Stationary Engineers.

daily record. The entire plant is equipped with recording Venturi meters, and if possible each unit is supplied with an indicating Venturi meter in the auxiliary feed line. Daily records of the recording meter are kept up and by means of the individual indicating meters the water consumption of a particular unit may be checked up at any time. Attached to each boiler is a Hays gas sampling tank, which may be adjusted to withdraw a sample of the flue gases for any period desired. The station is also equipped with the gas analysis instrument by which the engineer may analyse his various gas samples daily, or on each shift. This result should be posted in the boiler-room, with the name of the fireman indicated thereon, and any fireman not developing the required quality of gas is in line for some private instruction. A daily sample of the ash from each boiler is taken and analysed for combustible. This result is also posted in the boiler-room the following day with the number of the boiler and the fireman in charge thereof.

It will be found that competition between various firemen, or various shifts, will be immediately established, and the dome of the entire boiler-room will be removed almost automatically. If it does not have its result, the chief engineer has the information at hand that will enable him to apply the pressure in the right place.

Necessity for System

All of this might seem like an unnecessary expense and an impracticable proposition, but in the plant containing many boilers it is economy of a proper and essential kind. When the waste of heat up the stack and into the pit is measured in dollars and cents, there will be no question as to the saving to be effected by the above procedure, and all that is necessary to convince the skeptic, is to figure what it will cost to do this, and what it would cost not to do it.

The above system supplies the essentials for a continuous test, and the engineer-in-charge can daily check up his operatives, placing the blame for low efficiency exactly where it belongs, and thereby be equipped with the information necessary for the immediate elimination of the waste. As in other matters, eternal vigilance is the price of economy, to paraphrase a well-known author. The descent into efficiency is easy.

Automatic Steam Regulation

The economy of automatic steam regulation in a boiler plant, is of sufficient importance to warrant any manager or superintendent taking the time necessary to investigate it. The prime object of damper regulation is when the steam rises above the required pressure, and a great loss is being sustained by the engine being supplied with steam at higher pressure than it requires to do its work properly and easily, to so handle the feeding of the fuel and regulate the draughts that steam may be supplied to the engine as it may need it, and at constant and unvarying pressure.

It is practically impossible for the firemen to maintain steam at an exact pressure without mechanical aids. The varying load of an engine caused by the throwing on or off of the various machines throughout the plant or the different amount of work which these machines are required to do affects the amount of steam which is used by the engine.

If all the machines are working to the limit of their capacity the engine is taking a great deal more steam to keep them going at the proper speed than if some of them are idle of working light. The fireman has no means of knowing when the load is going to be light or heavy, the best he can do is to keep the steam at about the required pressure.

If the load, or in other words the amount of work which the engine is doing, should increase for a while or be kept at full capacity, the firemen would keep the hot fire under the boiler, in order to generate steam enough to keep the engine turning at its correct speed. Should the work slacken on the machines, which it will do for any one of a number of reasons such as the stopping of a certain set of machines, this action would lighten the load on the engine, causing it to take less steam through the action of the governor; but the fire under the boiler would keep on generating steam at this time, which the engine has no use for.

The result would be that the steam pressure would rise, and the safety valve release the pressure, thus allowing the excess steam to escape into the open air.

Waste Means Loss

This of course is a waste of steam, water, coal, and labor, which means a loss of money to the owner. This may be prevented by a damper regulator, just as an engine is prevented by the governor from running away. The damper regulator acts on the boiler just as the governor, acts on the engine. No one would think of asking the engineer to stand by the controlling valve of his engine in order to regulate the amount of steam it should have to keep it turning at a speed so as to produce the necessary amount of work throughout the factory.

We all know that the machines throughout a plant do their best work while running at a certain speed. Their speed is regulated by the size of pulleys attached to the line shaft. The speed of the line shaft is regulated by the engine. The number of revolutions made by an engine in a given length of time is controlled by the steam supplied to it by the boilers, and regulated to a certain extent by its governor. When the steam drops below the required pressure only a few pounds, the governor will keep the engine turning at the same speed, but it will be by the admission of more steam to the cylinder.

To maintain the engine speed, the steam consumed is increased in two ways, first, by its expansive power as the pressure is reduced. The higher the pressure, the drier the steam will be, causing quicker action and more expansive force, thereby doing more work with a less volume of steam. When the steam is low, the engine takes more of it to do the same work. This means that more water has to be evaporated, that more water has to be pumped into the boiler, which also requires more steam, all of which means that more fuel has to be burned in order to evaporate the extra water required to make the extra steam.

Automatic Damper Operation

If, when the steam is low, the full load is put on the engine by the operation of all machines in a plant, or an extra load on some of them, the machinery throughout the entire plant will drag, and the production of that day will be less than normal.

This condition may be prevented by the automatic damper regulator. When the steam reaches the given pressure it closes the upper or back damper, on the instant; it does not wait until the steam has gone over the mark, nor does it close it before the steam reaches the required pressure. By closing the back damper, the heat arising from the grate is held in the tubes and around the boiler, so that the damper may be shut longer, and the steam pressure remain up longer, without burning more fuel than would be burnt when the fireman closes the ash pit doors, allowing the heat to be free to pass on to the stack.

The latter method is resorted to when no regulation is used. When the upper or stack damper is closed, the air is entirely prevented from passing through the coal. Coal will not burn, unless supplied with air. This leaves the coal lying on the grates, but not burning, ready the instant the damper opens to start generating more steam, thus keeping a more even heat on the boiler and tubes, and preventing the contraction and expansion which causes so many leaky tubes.

When the damper is used the ash pit doors remain open, allowing the air to circulate under the grate bars, which keeps the latter in better shape and makes them last longer than they would if the ash-pit doors were closed, shutting out the air and allowing the intense heat of the furnace to strike down.

Where there are automatic stokers under the boilers, the damper regulator is connected with the stoker engines, as well as with the damper. When the damper closes, the stokers are slowed down so that the supply of fuel is checked until the damper opens again, and more fuel is needed. This is accomplished either by a mechanical connection to a quick opening valve, or by a water connection between the regulator cylinder and a pressure regulator on the stoker engine supply line. When burning gas or oil as fuel, an extra quick opening valve is used on the burner supply pipe, and the regulator opens and closes this valve as well as the damper. This cuts off the supply of gas or oil and insures a positive saving.

VICTORY FIRST, THEN—?

TO those who have listened to the appeals and exhortations from workers for the Victory Loan during the past few weeks, who have noted the presence in their midst of men prominent in the industrial world, who have studied the statements and weighed the remarks of those men with more than ordinary care and deliberation, one feature stands out above all other considerations and that is the unredeemable debt which every living soul in this country owes to each man and boy, yes and woman too, who have gone forth at the call of duty, and in many cases fulfilled it to the last.

Business men, manufacturers and others who could have stood back have gone amongst their workers and friends, and by virtue of their very earnestness and sincerity have influenced the indifferent and strengthened the willing to insure to the greatest possible extent the overwhelming success of Canada's Victory Loan.

Apart, however, from the sentiment of the situation and the disastrous effects which would have resulted had failure attended their efforts—a catastrophe which we now know is impossible—one feature which was given considerable prominence and which impressed many hearers hitherto unacquainted with it was the tremendous wealth of the Dominion in natural resources. To fully expound this phase of the country's effort would tax the powers of any student of political economy, but its true perspective at the moment can be faintly realized if one considers for a moment just how much visible wealth there is now in this country, both individual and corporate, and that such wealth, in case of emergency, would become national.

The immense sum represented by this is the result of approximately only half a century's development and is therefore but a fraction of what will be in existence in the next half century, yet all this that we call wealth is but evidence, some of it tangible, some of it intangible, of the value of this part of the North American continent as a habitation for mankind.

While in some respects our country has been blessed through the absence of war's terrors, the fact of such immunity may be ultimately a handicap which will demand increased effort on our part to overcome. The demands of war have been felt most intensely and insistently in Britain and France, and later in the United States. The former countries, however, by reason of their previous dependency on Germany for many essential materials, were called upon to make efforts beyond comprehension at this distance, efforts which have resulted in many industrial developments that ultimately will more than compensate for the present strenuous times.

It is here that we, with our latent potentialities, must be fully alive and awake to the probabilities of the future. Much is said of our enormous water power resources, but when munitions and stores of war vanish from the factories, when nations cry aloud for the necessities of life, when efforts to make the world a place to live in are resumed on an unprecedented scale, shall we be willing and able to apply that wealth which is our present strength to the amelioration of the lot of those of our brethren whose bravery and sacrifice has been our present protection?

It is there that our future duty lies, not scarred with battle and torn with strife, but clothed with humble reward and a due appreciation of our debt to others. While our men and dollars are fighting let not our brains slumber. The race will be to the swift even as the fight is now to the strong.

WITH BEST WISHES TO ALL

THE approaching close of another year is marked by a seriousness in world affairs exceeding any previous occasion, a seriousness which is intensified because its consequences are more freely realized than during similar crises hitherto.

The Festive Season, so strangely sounding in these times, has become, instead an annual period whereby the sufferings of millions are recorded. Joyousness has been replaced by grim determination—happiness is held in abeyance.

To all of our readers we extend heartiest wishes for a Brighter New Year, to those of them sharing in world-wide bereavement we offer our sincere sympathy, and those who have co-operated in making POWER HOUSE valuable and instructive during the past year are assured of both our readers' and our own appreciation of their efforts.

Association and Personal

PERSONAL

L. W. Adam of Bethlehem, Pa., has been appointed to the position of General Superintendent of the Nova Scotia Steel & Coal Co's. plant at Trenton, N.S. Mr. Adam will reside at New Glasgow, N.S.

Lawrence Russel, who for several years has been sales manager of the Armstrong, Whitworth Co. of Canada, Montreal has been appointed assistant general manager of the company.

Herbert Johnston of the sales staff of the Armstrong, Whitworth Co., Montreal, has been appointed city sales manager, to succeed L. Russel, recently appointed assistant general manager.

John Ross, general superintendent of the mill of the Abitibi Power & Paper Co. at Iroquois Falls, Ont., was caught in the transmission and instantly killed recently. Mr. Ross was one of the highest paid paper experts in America and had been employed at the Abitibi about one year. He was forty-two years of age.

Capt. Arthur J. Latornell, B.A.Sc., at one time city engineer of Edmonton, Alta., has died of wounds received in action in France. Capt. Latornell, a Huguenot by descent, was born in Meaford, Ont. After graduating with honors in civil engineering, Capt. Latornell became city engineer of Edmonton, an appointment which he gave up early in 1916 to qualify for an overseas commission.

Henry J. Fuller, president of the Canadian Fairbanks-Morse Co., has been elected president of E. & T. Fairbanks & Co., of St. Johnsbury, Vt. The election of Mr. Fuller to this office will unite more closely the Canadian and American organization. Mr. Fuller is also a director of the Canadian Bank of Commerce, the National Trust Co. and other industrial concerns in the Dominion. Although born in St. Johnsbury, Vt., Mr. Fuller came to Montreal in 1897, two years after completing his education at Worcester Polytechnic Institute, and established a branch of the Fairbanks Co., which later developed into the Canadian Fairbanks-Morse Co., of which he is now the chief executive.

Toronto Lodge C.A.S.E. Social.—The members of the C.A.S.E. Lodge, Toronto, held their annual "Get-Together" social in the Banquet Room, Temple Building, Bay Street, on Wednesday, November 21. Members and wives, numbering about seventy, thoroughly enjoyed the social, which was a great success. The proceedings opened with a concert, the principal numbers including the following: The Oakwood Quartette, G. Cole, Jr., solos; S. Balmfirth, monologue; John Reid, Scotch songs. Mrs. S. Balmfirth played the opening piano solo and accompanied the singers. The mucis was followed by euchre and refreshments.

PHYSICAL CHARACTERISTICS OF SULPHUR DIOXIDE

THE subject of sulphur dioxide was the subject of some remarks by a writer in an English contemporary in the course of which it was pointed out that the cold producing medium is sulphur dioxide. designated as SO_2, and not sulphurous acid, the chemical symbol of which is H_2SO_3. The gas is obtained principally by burning sulphur in air, when theoretically an exact proportion of oxygen is taken up to provide the compound; water vapor or additional oxygen, however, may also be absorbed. If sulphur is strongly heated it melts to a brown fluid mass which readily ignites and burns with a bluish or lilac flame giving off a powerful odor due to evolution of sulphur dioxide. The gas may also be prepared from compounds containing sulphur and from pyrites, i.e., iron sulphide or disulphide, but not satisfactorily. When the SO_2 comes in contact with moisture, sulphurous acid is obtained, which is converted into sulphuric acid (H_2SO_4) by additional oxygen.

Since it is practically impossible when burning sulphur to regulate exactly the supply of air or oxygen, the gas is likely to attract extra oxygen and form SO_3, sulphur trioxide, or sulphuric anhydride. And since it is equally difficult to obtain absolutely dry air a certain proportion of sulphurous acid will occur since sulphur dioxide combines at once with any moisture that is available. Even if an apparently dry gas is obtained, the minutest leaks in the joints of apparatus through which it is conducted admit air and moisture and these gradually form sulphurous acid and sulphuric acid. While the flame of burning sulphur is colored, the gas itself is colorless. It is twice as heavy as air and is very acid.

OPERATOR ORGANIZATIONS

British Columbia Association of Stationary Engineers, Vancouver.—Subordinate Lodges at Vancouver, Victoria, New Westminster, Cumberland, Merritt, and Fernie.

Secretary.—John H. Hale, Hamilton, Ont.

TORONTO LODGE C.A.S.E.

AN interesting and instructive series of addresses of talks have been arranged to be delivered before the members of C.A.S.E. Lodge No. 2, Toronto. The subjects selected are all of live interest to operating engineers, and will form a regular feature of the meetings this winter. Three papers have already been read: "The Development of the Steam Boiler," by S. Balmfirth; "Chimneys and Drafts," by A. M. Wickens; and "Feed Water Treatment," by T. B. Allen, of the Allen Mfg. Co., Toronto. For future papers the dates and speakers have not all been decided upon. One paper will, however, be read by L. O. Smith, of the Power Plant Equipment Co., Toronto, the subject being the "Skinner Uniflow Engine. A paper on "Hot Water Heating" will be submitted by S. Balmfirth, and the chief engineer of the Monarch Supply Co., Toronto, will address the members on the subject of "Steam Heating." Papers will also be read on the following subjects: "Pumps and Injectors," "Steam Engines," "Combustion, Firing and Draft," "Economical Combustion of Coal," and "Ventilation." The paper on the "Skinner" engine is a special talg, and the date is not settled, but the meeting will be open to friends of the members. A discussion will follow the reading of each paper, which will lend additional interest to the proceedings. The lodge meetings are held in the Temple Building, Bay Street, on the second and fourth Wednesday in the month. The next meeting is on Dec. 26.

The Operators' Point of View

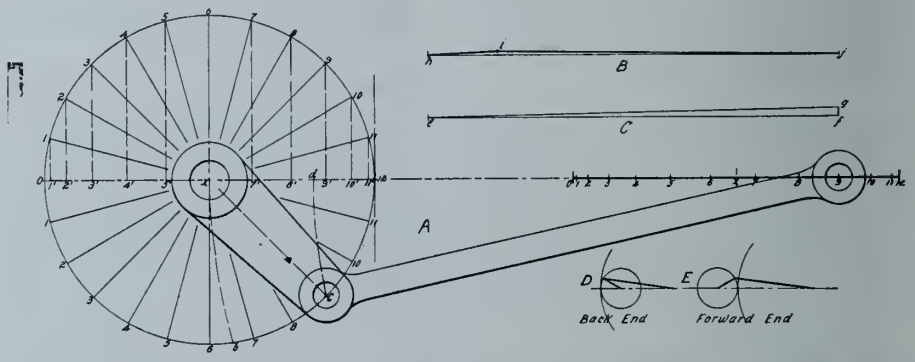
DOES A PISTON STOP AT REVERSAL?

By R. Hamilton

CONSIDERABLE interest has apparently been shown by many readers in the question, does a piston stop at reversal? This is one of those mechanical conundrums that, in itself, has little or no bearing on the actual operation of an engine, but one that will awaken the deepest curiosity in the majority of engineers or mechanics, once they are fairly confronted with the problem. An impromptu reply to this query would invariably be, that the piston does stop at each end of the stroke; but after a little study of the linkage involved, together with the underlying principles of geometry, many are forced to take a neutral stand regarding its proper solution. In the opinion of the writer there are reasonably two answers to the question; that is, theoretically—with absolutely no lost motion in the various connections—the piston does not stop at either end; practically, the piston does make an infinitesimal stop, owing to the fact that it is impossible to make a fit of two moving parts that will be entirely free from lost motion. This looseness, even though imperceptible, is nevertheless present.

On the basis of a theoretical solution, we must realize that if a stop is made it will be when the engine is on either of the dead-centers; that is, when the center of the crank, the center of the crank-pin and the center of the cross-head pin are in the same straight line. We know that this condition exists during each revolution of the crank; so the question now is, how long are these three centers in the same straight line? The geometrical definition of a line is that it has only one dimension, that of length. Therefore, if it has no thickness and the crank is in motion, there can be no stop on the line. The two extreme positions on this line constitutes the points known as the dead-centers of the engine. Again we are faced with the definition that a point indicates position only; it has neither length, breadth or thickness. As the circle described by the crank-pin is not a straight line, it is a logical conclusion that no portion of it is a straight line; so that it is quite obvious that, on the forward stroke the maximum distance between the center of the crank and that of the cross-head is not attained until the dead center is reached, when the action of the cross-head, and other reciprocating parts, is immediately reversed.

A factor that should be thoroughly understood in the study of this problem, is that of the relative motion of the crank and cross-head pins. The uniform motion of the fly-wheel causes the crank-pin to pass through similar circumferential distances in the same period of time. When this rotary motion of the crank is converted—by means of the crank and connecting rod—into the reciprocating movement of the cross-head and piston, the action of the cycles are uniform, but each cycle of the reciprocating parts consists of a gradual accelerating and retarding motion, occurring twice in each revolution of the crank.



ILLUSTRATING REMARKS BY R. HAMILTON WITH REFERENCE TO REVERSAL OF ENGINE PISTON.

By referring to the sketch it will be seen that the crank-pin circle is divided into a certain number of equal parts, illustrating the uniform action of the crank-pin. If the reciprocating motion were obtained by means of a slotted link, the corresponding positions of the cross-head or piston would be indicated by the points on the horizontal diameter derived from the vertical projection of the points on the crank-pin circle. However, with the general practice of using a connecting rod, as here shown, there is a slight variation in the acceleration at either end, due to the angularity of the connecting rod. This is clear from the arcs X-B and C-D. The graduations on the line O-12, to the right, represent the horizontal movement and position of the cross-head for the corresponding positions of the crank-pin.

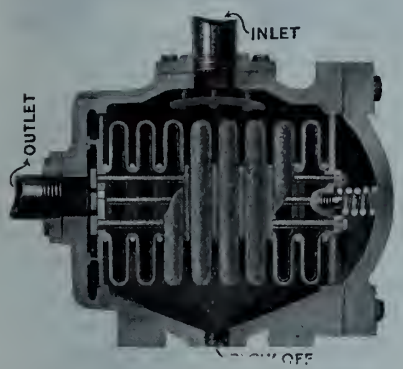
The position of the cross-head can be readily determined when the crank is at any point in its path of travel. By using the length of the connecting rod as a radius and striking an arc from the center of the crank-pin to the horizontal diameter, this intersection will be the relative position of the cross-head between its extreme points of travel. The variation in the retarding or accelerating motion of the reciprocating parts may be better understood by referring to sketches D and E. When the crank-pin is approaching the back end dead-center, the crank and the connecting rod are overlapping, and the arcs that would be described by their outer ends would be tangent in the same direction, whereas on the forward end the opposite action evidently takes place, with the obvious result, that for the same arc traversed by the crank at either end, the speed of the reciprocating parts would be greater at the forward end, as indicated in the lengths O-1 and 11-12 on the graduated cross-head traverse line.

In order to form a triangle we know that the sum of two of the sides must be greater than the length of the third side. With the exception of the "dead-center" positions, this condition always exists in the constantly changing positions of the moving parts under discussion; therefore the solution of the "stop" query may rest on these facts. A skeleton diagram of the linkage approaching the forward "dead-center" is the straight line H-J, the triangle is still shown at B; 1 representing the crank-pin. Until the point 1 coincides with greater than H-J; but, as a line has no existent, and the length H-I-J must be magnitude, the time required for the crank-pin to pass over or through it must be nil—therefore no stop is possible (theoretically). Diagram C is an exaggerated skeleton sketch of the center line of the crank nearing a "dead-center;" E-F-G forms a right triangle, E-G being the hypotenuse, so that the latter must exceed the length E-F until it is in a direct line with it. Some of our readers might advance their arguments as to how long it takes the crank-pin to pass this "line."

Progress in New Equipment

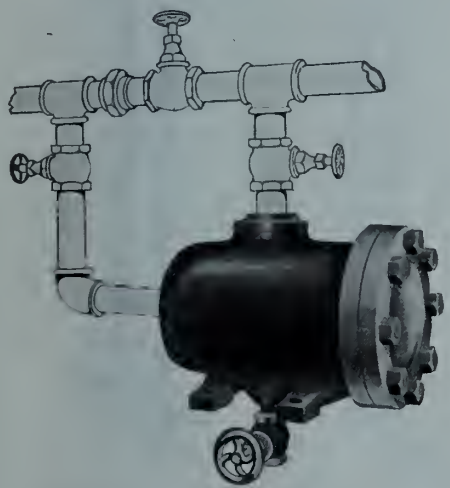
FEED WATER FILTER

THE accompanying illustrations show an interior and exterior view of the Reliance Feed Water Heater, designed, among other things, for the removal of oil from boiler feed water, specially adapted for marine purposes. As seen in the sectional view, the unfiltered



INTERIOR VIEW OF "RELIANCE" FEED WATER FILTER.

water enters at the top and passes into central portion of the chamber, being distributed in all directions by means of the convex disc, which prevents the direct force of influx from striking the fabric material on the outer portion of the cartridge. The cartridges are composed of thin copper perforated discs, covered

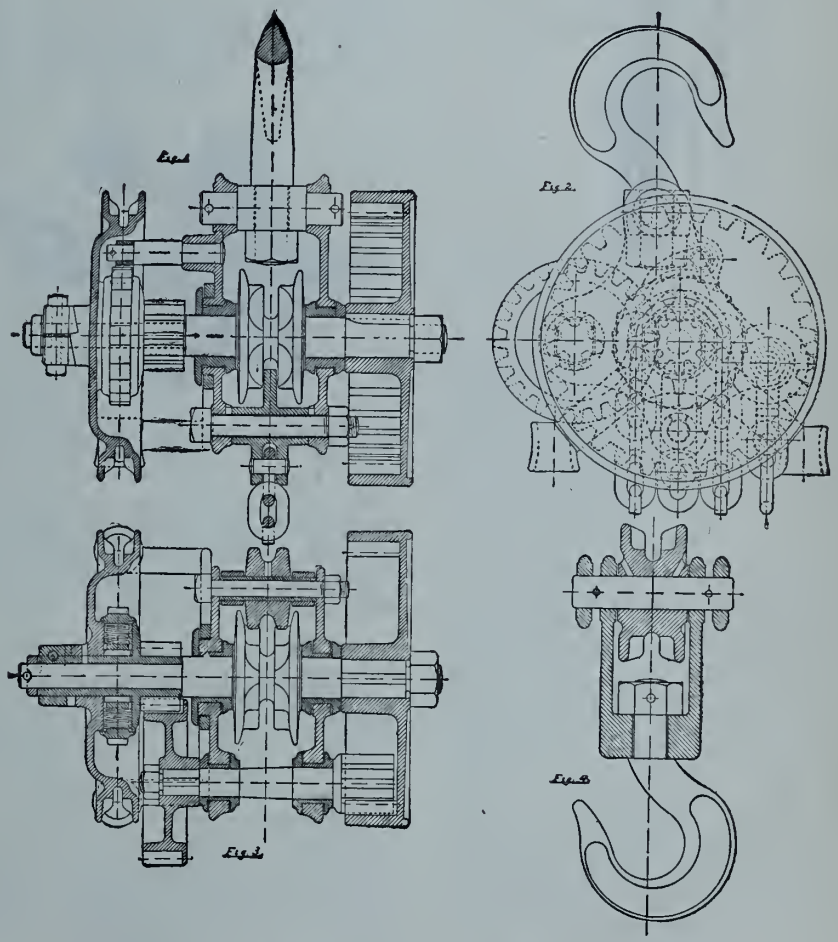


"RELIANCE" FEED WATER FILTER, SHOWING PIPE CONNECTIONS.

with Turkish towelling, through which the water must be forced before it enters the discharge outlet; this causes the oil to be entirely separated and can be blown off at intervals. When installing this filter on the pipe line, it is necessary to provide a by-pass, so that the filter can be cleaned without shutting off the boiler supply. To reduce the "out-of-service" time to the minimum, an extra cartridge is supplied so that the lost time is only that required while the cartridges are being changed. Cleaning can take place while the other cartridge is in service. These filters are manufactured by Darling Bros., of Montreal.

TWO-SPEED CHAIN HOIST

THE accompanying illustrations show the mechanical construction of the Simplex chain hoist, one of a line of hoisting specialties manufactured by J. G. Speidel, Reading, Pa., a novel feature of the apparatus being the simple and ingenious method of securing two speeds.



SECTIONAL VIEWS ILLUSTRATING OPERATION OF TWO-SPEED CHAIN HOIST.

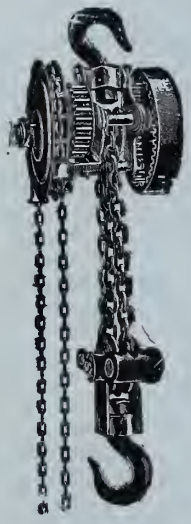
An endless hand chain is laid over the large chain wheel, which, in connection with a pinion and a brake wheel with ratchet teeth in the outer rim, form the automatic brake, which keeps the load from running down. These three parts, when put together, are handled like one piece, and turn loose on the reduced extension of the main shaft.

The pinion attached to the hand chain wheel drives a spur gear, which is keyed to a second shaft, at the end of which is another pinion, which engages with the teeth of an internal spur gear, which is keyed to the opposite end of the main shaft, to which is attached the lift chain wheel. Thus, by means of two pairs of spur gearing, motion is transmitted from the hand chain to the lift chain. By pulling on the hand chain, in one or the other direction, the load is either lifted or lowered.

In hoisting the load the brake wheel, with its ratchet teeth on the outer rim, revolves freely with the hand chain wheel and pinion, not causing any resistance, the ratchet pawl running freely over the teeth. As soon as the pull on the hand chain ceases, the pawl engages with the ratchet teeth on the brake wheel, keeping it from running backward, and so keeping the load suspended.

In lowering the load the hand chain is pulled in the opposite direction, and a slight pull is sufficient to overcome the friction of the automatic brake, thus allowing the load to descend and holding the same suspended again as soon as the operator stops pulling on the hand chain. By a continuous pull on the hand chain the load can be lowered at a good speed.

Features of the design which make for positive action and flexibility of control are as follows: A pawl arrangement in



EXTERIOR VIEW OF TWO-SPEED CHAIN HOIST WITH AUTOMATIC FRICTION BRAKE

the lower block, which locks the hoisting chain to the sheave, allowing light loads to be hoisted at double the speed used when working to capacity load; the guides through which the hand chain passes are closed rings attached to a swinging frame, which permits them to take up the position of least resistance when the chain is pulled at any angle, thus allowing the operator to stand well out from beneath the hoist without imposing undue wear on the chain and guides; the lift chain is prevented from jumping over the sprocket of the lift chain wheel by means of a guide roller, and a stripper, which runs up through the narrow groove of the lift chain wheel prevents the chain from sticking to the wheel.

This hoist is supplied in capacities ranging from 1,000 pounds up to 40,000 pounds, and it is claimed that one man can lift any load up to 16,000 pounds, above which two men are required.

STEAM TURBINE FOR FANS, BLOWERS AND PUMPS

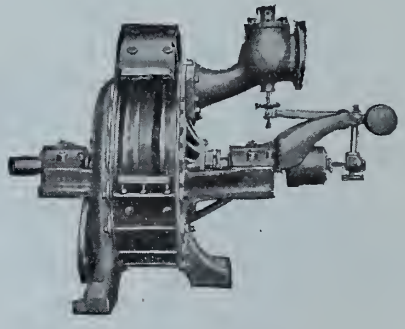
THE Canadian General Electric Company is offering a Curtis Steam Turbine in a wide variety of capacities to drive fans, blowers and pumps for boiler feeding and circulating systems.

It is called the type L and is of the impulse type. The number of stages and rows of buckets vary with the capacity. The principles used and mechanical practice evident in the construction are the result of the vast experience of the manufacturers in producing turbines for practically every class of service.

A split wheel casing is used to permit ready inspection of the buckets which are of bronze securely dovetailed into the rim of the wheel. The exhaust steam is free from oil and is well suited for heating feed water.

Special regulation is close and reliable and the speed may be changed by hand wheel adjustment while the turbine is in operation. A constant running speed is maintained by a simple and powerful speed governor mounted directly on the shaft and controlling a double balanced piston valve type throttle.

The main shaft carrying the turbine and governor runs on babbitted bearings with renewable linings, and is fitted with



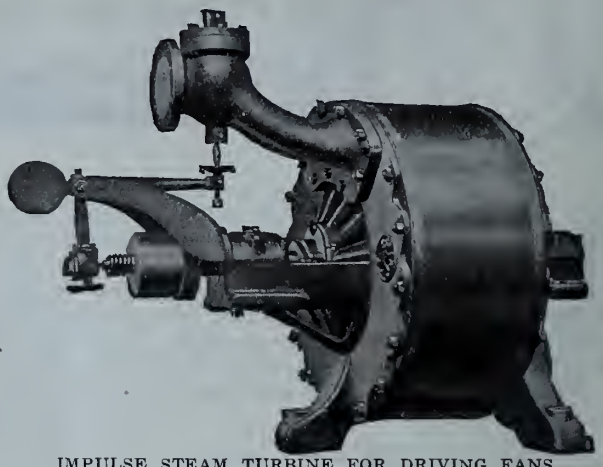
SHOWING SPLIT WHEEL CASING OPENED FOR INSPECTION.

readily accessible packing glands.

Three feet support the rigid frame of the turbine to insure the bearings always being in line. The wheel casing is neatly lagged with planished iron.

THE LONG STEAM TRAP

SIMPLICITY combined with efficiency are the two essentials in the successful operation of any piece of mechanical equipment, and this is increasingly emphasized where there is a possibility of certain parts of the mechanism getting out of order and thereby destroying or seriously affecting its usefulness. Wherever steam is used it is very important to instal traps at certain points to prevent the formation of condensation in the pipe line; both as a feature of effective operation and also as a factor of economy. The accompanying cut illustrates a simple device for freeing steam pipes of condensation, the limited number of its parts minimizing the danger of unsatisfactory operation, through the disarrangement or failure of moveable portions. The operation of this trap is controlled by the expansion and contraction of the thin inner tube, acted upon



IMPULSE STEAM TURBINE FOR DRIVING FANS, BLOWERS AND PUMPS.

by the variation of the steam and water temperatures, the construction being so sensitive as to operate at a variation in temperature of one degree. A feature of the trap is that it can be installed in any position to suit the layout of existing equipment, but where it may be subjected to freezing temperatures it is necessary to instal it in a horizontal

SECTIONAL AND EXTERIOR VIEW OF "LONG" STEAM TRAP WITH OPTIONAL OUTLETS.

draining position, to insure continuous operation. One of the most troublesome conditions of steam distribution is the formation of air in the pipe lines, and the action of the trap here shown as-

SEGMENT OF BOILER GIRTH SEAM PROTECTOR

sures the expulsion of all air and water before the regular operation of the trap commences.

After the installation of one of these traps, the only necessary requirement is that steam be allowed to pass through freely until the entire trap is thoroughly heated, and, when such has been attained, the valve is set with just sufficient pressure to close the opening, so that, as the steam commences to condense, the slight decrease in temperature causes the inner tube to contract and permit the water to escape, and when steam again enters the opening is again closed. This continues regularly and indefinitely. Another advantage is that it will operate against pressure, as it may be desired to force the hot water to a higher level for specific purposes, such as the washing of bottles, etc. The two outlets are an added advantage to the trap, as it may be fitted as a small condenser without destroying its draining qualities. These traps are made in only one size, weighing approximately 5½ lbs., and are capable of draining the equal of from 1,000 to 1,500 feet of one inch pipe. J. T. Long, 84 Adam St., Montreal, is the manufacturer of this device.

BOILER GIRTH SEAM PROTECTORS

A TROUBLE always resepnt in horizontal tubular boilers is that arising from cracks on the boiler shell surface, directly above the fire chamber. These defects invariably originate at the girth seam, which, owing to the general construction of this type of boiler, is located immediately above the fire, where it is exposed to intense heat. The heat in itself is not the objectionable feature, but owing to the necesity of fire, this portion is subjected to continually varrying stresses, caused by the frequent expansion and contraction of the plates. In an effort to minimize this trouble boilers have been designed where the section exposed to the high temperature of the fires, has been made in one piece, to bring the seam in a position out of the direct action of the hot gases. Owing, however, to the great area required, this method has not given satisfaction, and the seam has still remained more or less a source of trouble and inconvenience.

A simple device for preventing the formation of fire cracks that has been recently perfected, and for which patents have been granted, has been placed on the market, and installed on a large number of boilers, both in the United States and Canada with remarkable results. It is claimed that a boiler equiped with this seam protector will be permanently protected from all danger of fire cracking and subsequent leakage resulting therefrom; an unprotected seam that has developed a leak can be caulked tight and fitted with this device, and the claim is made that the seam will remain dry indefinitely. The illustrations herewith show a general view of the detached show a general view of the detached parts and the method of applying to the boiler shell. It will be seen that the application of this seam protector is very simple and that it does not interfere with the heating qualities or detract from the strength of the seam. As a matter of fact, the construction of the protector, with the large semi-circular sections of fire brick or reinforced asbestos, provides a reserve of heat that prevents any sudden reaction in the seam when the fire door is opened or closed. As the cold outside air from the open door or the hot gases from the fire are not permitted to come in direct contact with the boiler seam, the effect is to retain a uniform temperature on the outer lap, thus avoiding sudden or violent contraction or expansion of the lap.

In addition to preventing exterior fire cracks, it has been demonstrated that the accumulation of sediment along the edge of the inner lap, and about the heads of the rivets—a condition that is generally the cause of interior mud cracks—is largely, if not entirely eliminated, as the retaining of a more uniform temperature at this particular point has shown the tendency to prevent the formation of injuries muddy scale that bakes to this portion of the seam, when the same is exposed to the direct action of the fire. It is thereby claimed that these protectors have made the weakest portion of the boiler equally as strong and durable as any other part.

In fitting this boiler seam protector to units already in service, two adjacent rivets, at suitable distances apart, on the girth seam, are notched by means of a special diamond point chisel as shown at AA to receive the wedge nut B, this being made a snug fit. When same is in position, the metal lug or tile support D is attached by means of a small ½ in. bolt C. When this is firmly placed, the fire brick or asbestos tile E is slid over the extending lugs of the cast iron piece D. Each one of these units is placed approximately 9½ in, apart, and five or more may be required to cover the length of the affected seam. This seam protector is not only used on stationary boilers, but is applicable to all fire exposed seams on locoomotive and marine boilers. These seam protectors are manufactured in Canada by the National Boiler Protector Co. of Canada, 382 St. James Street, Montreal.

A CONTRAST

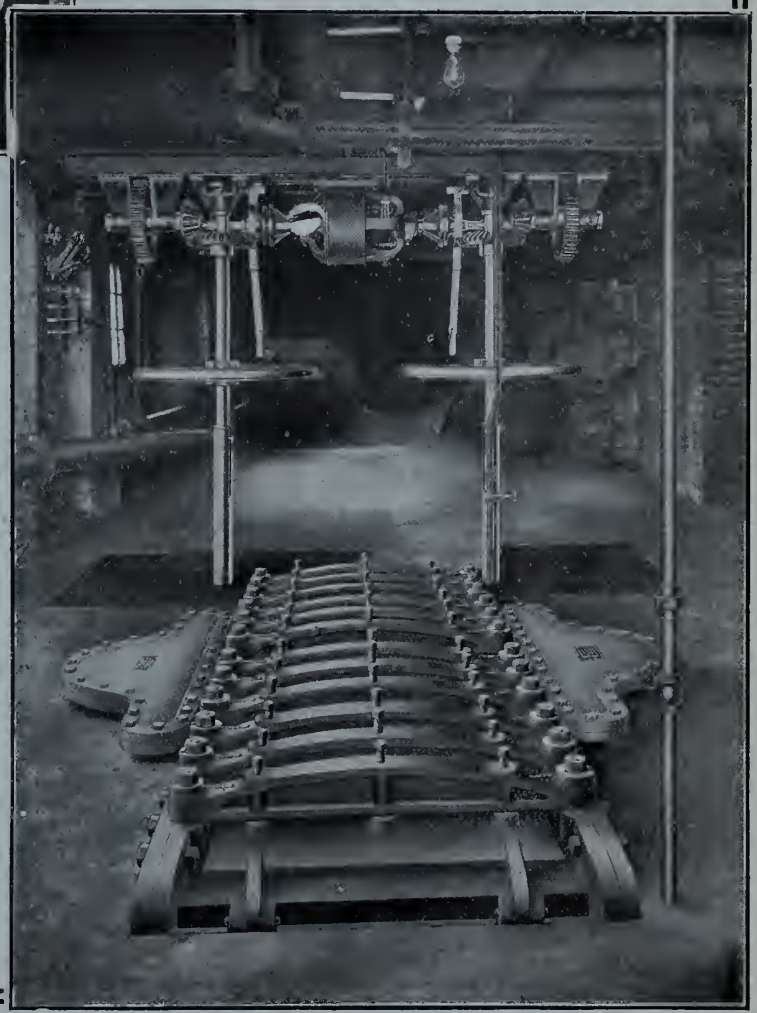
The photograph opposite shows one way of keeping such debris as sticks, leaves, etc., from being drawn into your pumps, condensers and other apparatus.

A diver is engaged periodically to go down under the water to remove the debris that accumulates around the strainer on the inlet of the intake pipe.

The photograph below shows another way of keeping debris from entering your plant via the water intake plan.

A Twin Strainer is used to catch all solids, such as fish, sticks, leaves, twigs, stones, etc., that are carried along in the water. These solids are retained in the baskets of the Strainer, where they can be readily removed at any time without interrupting the flow of water, for when the water is flowing through one set of baskets the other set is out of service.

Motor operated Twin Strainer in 42-inch suction line to condenser—Toledo Railways & Light Company. The motor and operating apparatus is overhead, where it will not be damaged during high water seasons.



Some of the many advantages of the Twin Strainer installation will be readily apparent.

The most obvious one is the convenience of cleaning, which is an assurance against interruptions to the service. The Twin Strainer can be cleaned once or forty times a day, as conditions demand. It can be located in any convenient place inside the plant, where it is accessible at all times.

Twin Strainers will strain water, oil, or any other liquid, and are furnished for either motor or manual operation, in all sizes from 1 to 48 inches inclusive. The basket equipment is varied to suit conditions. Complete information in Bulletin "A." A copy is yours on request.

Elliott Company

6902 Susquehanna St., Pittsburgh, Pa.

This Trap can be installed in any positiondesired as it has two outlets

This is a remark very often made by users in reference to—

The

LONG Patent Steam Trap

Has But One Movable Part

Valve is actuated by the expanding and contracting of a tube, a motion that is positive and of sufficient force to close the valve against a pressure of two hundred pounds.

The Long Trap is automatic and requires no valves except those which control admission of steam to apparatus to which trap is attached. It is capable of draining from 900 to 1,500 feet of one-inch pipe. There are other superior points about the Long Steam Trap, as it could be used as a condenser for heating water for washing bottles, etc., and still remain a trap. Let us tell you the complete story of this wonderfully successful power house facility.

Trade Gossip

Thorold, Ont.—A hydro-electric by-law will be submitted to the ratepayers.

Winnipeg, Man.—The Prest-O-Lite Co. will build a factory at St. Boniface, to cost $10,000.

Lumsden, Sask.—The Town Council will appropriate $7,000 to acquire the plant and equipment of the local electric light and power company.

Whitby, Ont.—The by-law granting a loan of $25,000 to the United Rubber Mfg. & Reclaiming was passed by the ratepayers by a large majority.

Oshawa, Ont.—A shoe factory may be established here if satisfactory arrangements can be made with the council by the company interested in the project.

Aikenhead Hardware, Ltd., are now distributors for Canada of the Simplex two-speed chain hoists manufactured by J. G. Speidel, Reading, Pa.

Sault Ste. Marie, Ont.—Fire on Dec. 3 of unknown origin caused a loss of several thousand dollars to the Standard Chemical Co. plant. The loss in the latter fire was $7,000.

Orangeville, Ont.—It is reported that the local cement plant, which has been idle for four years, has been sold to a Kingston concern who propose manufacturing a fertilizer.

Toronto, Ont. — The Massey-Harris Co. have taken out a permit to build a dry kiln on the west side of Shaw street, near Strachan avenue and King street, to cost $5,000.

Chatham, Ont.—The T. H. Taylor Co. is in the market for a complete outfit of Jones under feed stokers, and for two boiler installations, including engines and fans, etc.

Toronto, Ont.—A building permit has been issued by the City Architect to the Liquid Air Society to erect a one storey tile and steel addition to their factory at 18 Boler street. The cost will be $2,600.

Galt, Ont. — The City Council have passed two by-laws, one to pay $45,000 on extensions to the hydro-electric system and another to extend the waterworks system at a cost of $18,558.

Toronto, Ont.—City Architect Pearse has granted a building permit to the Bank of Hamilton to erect a three-storey brick bank building at 341 Yonge street at a cost of $4,000.

Toronto, Ont.—Permission has been granted the T. Eaton Co. to erect a one-storey brick delivery building, to cost $45,000, at the corner of Coxwell avenue and the G.T.R. right of way. Building operations have already been commenced.

Japan Needs Steel Plates.—Japan cannot continue much longer to aid the Entente Allies with shipping unless permitted to import steel plates from the United States, Baron Megata, head of the special Japanese finance commission, said at a dinner given by Japanese bankeds in New York recently.

Firm Changes Back to Old Name.—The directors of the International Engineering Works, Ltd., Amherst, N.S., have decided to change the name of the concern to Robb Engineering Works, the former title. A meeting of shareholders will be held in Montreal on Dec. 19 to confirm this arrangement.

The Dominion Bridge Co., Montreal, have obtained a controlling interest in the International Engineering Co., Amherst, N.S., and will carry on the business as a subsidiary. It is understood that the Dominion Bridge Co. have secured contracts for steam turbines and boilers in connection with the marine end of the business.

Sherbrooke, Que.—The city attorney has been instructed to prepare a by-law authorizing the city to issue debentures to the amount of $150,000. This sum is made up as follows: New power dam, accessories, generators and turbines, on Frontenac street, $116,000; turbines, transformers, regulators, tools and apparatus at Rock Forest power station, $34,000.

Montreal, Que.—At the annual meeting of the Mechanics' Institute held at Montreal recently, it was decided to begin the erection of the new building on the site purchased on the corner of Atwater avenue and Tupper streets, next spring. The building will include a reading room, library, lecture room, class or club rooms and a smoking room. The bulding, fully equipped, will cost in the neighborhood of $100,000.

Toronto, Ont.—Works Commissioner Harris has recommended that the Board of Control instal air chambers at the main waterworks pumping station. He explained that the air chambers were needed to safeguard the works from damage to the machinery in case of any temporary suspension of the Hydro service which might occur. Commissioner Harris estimated that the work would cost about $50,000. He was authorized to receive tenders for the work.

U.S. Price-Fixing Power.—Early enactment of legislation extending the United States Government's price-fixing power is expected by administration officials to follow President Wilson's declaration in his message to Congress that authority in this respect is now too limited. The feeling has been growing here that more power is needed to keep down rising prices; and industry, speaking through the Chamber of Commerce of the United States, has declared for the widest possible powers for the Government in this respect.

Dominion Resources Directory.—The first comprehensive and authoritative directory of Canada's natural resources is to be published without delay by the Commission of Conservation. Sir Clifford Sifton, the chairman, gave the first intimation of this at the annual meeting of the Commission last week. Inventories of the various sections of the country will be arranged, and published geographically, provinces having similar resources being grouped together. One

division, for instance, will cover the Maritime Provinces, another the Prairie Provinces, another Ontario, etc. The information to be published, it is believed, will be of the utmost importance in the solution of after the war problems.

The International Business Machines Co. has been launched with a capital of $2,000,000. The new concern will take over the plants and stocks of the International Time Recording Co. and the Computing Scale Co., both Toronto concerns, and the Canadian Tabulating Machine Co., of Montreal. The operations of this latter concern will be at once transferred to this city. By bringing these three companies together a great saving in the cost of management and operation will be effected. Thomas J. Watson will be the president of the new combination, and F. E. Mutton the vice-president and general manager. J. S. Ogsbury is the secretary. L. A. Davidson has been appointed sales manager for the scales division and St. George Bond, of Montreal, will have charge of the tabulating section. The company has $100,000 in cash available for immediate expansion.

Grecian Magnesite Exports in 1916.—Magnesite exports of all grades from Greece in 1916 are given as 176,383 tons. Of raw magnesite the United Kingdom took 60,511 tons; the United States, 56,504 tons; France, 24,607 tons; Italy, 3,100 tons; the Netherlands, 320 tons. Of the caustic and calcined mineral the United Kingdom took 13,127 tons, the United States 9,514 tons, and the Netherlands 730 tons. Of the dead burned grade, the United Kingdom took 3,975 tons and France 3,462 tons.

Lake Superior Ore Shipments.—A record for the month of November in the movement of ore from the Lake Superior district was established last month, when the cargo carriers on the lakes loaded 7,331,804 tons, according to figures just issued. This is an increase over November, a year ago, of 1,616,351 tons, and brings the season's total to December 1, up to slightly more than 61,500,000 tons. The season's total, however, is approximately 2,000,000 tons less than for the same period last year.

Coal Shipments on Lake Superior.—The up-lake coal movement to December 1, was 25,855,737 tons, or 1,938,675 tons greater than for the corresponding 1916 period. Coal movements have virtually ceased, but the year's total likely will exceed 26,000,000 tons. Abnormally heavy uplake coal movement offers a partial explanation for the shortage which prevailed in eastern Ohio and western Pennsylvania industrial districts for months past, greatly crippling operations and reducing the iron and steel output. Coal movement virtually stopped on Dec. 1.

Forest Survey in Ontario.—The Commission of Conservation hopes soon to undertake a survey of the forest resources of Ontario, similar to the investigations it has already made in British Columbia and Saskatchewan. Only

Trap Every Steam Line with a SARCO

High Cost of Steam

versus

Low Cost of Trapping

There was a time when steam was cheap. Not now. Now it costs more than at any time within a hundred years.

There was a time when all steam traps were expensive, big, cumbersome, troublesome things.

Not now. Now you can use the Steam Trap SARCO, which is small, low-priced, absolutely efficient and reliable, and goes right on any line anywhere.

Many untrapped lines steal the cost of a Sarco every week.

The Steam Trap SARCO relies on the expansion of a heavy hydrocarbon oil operating a Sarco Spiral Tube with a renewable cartridge. When steam reaches the cartridge, the trap closes and no steam escapes. When condensation collects the trap opens and discharges it.

NON-CORROSIVE
CYLINDER OIL
MANUFACTURED ONLY BY
E. H. KELLOGG & CO.
NOS. 242 & 244 SOUTH ST. NEW YORK, U.S.A.
FRICTION LOSS

An overload is often a necessity. But it is hard on an engine. To successfully carry an overload so that there will be no after effects on the engine a very careful selection of your oil should be made. An oil that is not free from impurities will cause a greater wearing on the bearings, a great friction loss will occur. You will need to fire the boiler more often because the engine will be harder to run. In this manner you lose out. You work harder, have larger operating costs, and less power all because of your oil. Do as a great many Canadian engineers have done — give Kellogg's "Non-Corrosive Cylinder Oil" a trial. Absolutely pure. Write us regarding it.

MacKINNON STEEL CO.

the most fragmentary data respecting the forests of Ontario are now available, although there is a vast amount of detailed information in the possession of timber owners, Government officers and railways, which could probably be secured. The commission is handicapped in undertaking such an investigation by the scarcity of competent foresters. Last year at the height of the fire season its staff consisted of about 1,000 men.

Shortage of Hydro Power.—The increasing shortage of hydro power has prompted the Hydro-Electric Commission of Ontario to develop an additional 45,000 h.p. at the Ontario Power Co's. plant at Niagara Falls. It is expected that this will relieve the situation until the Chippewa Creek development is in operation. The Chippewa development will furnish 300,000 horse-power and will cost something in the neighborhood of $23,000,000. The Western Ontario natural gas, which has been providing the motor power for many important industries, is falling down, and unless these people can get Hydro power several flour mills will have to suspend operation. Several companies are appealing to the Hydro to help them out now that they can't get natural gas.

Entertained Employees. — The employees of the Hall Engineering Works, Montreal, were recently given a dinner by the directors of the concern at Cooper's restaurant, there being about one hundred persons present. Toasts were given and a musical programme provided. A toast to the employees was proposed by T. Fisher, and responded to by W. F. Fletcher, director, and Wm. Forbes. In the course of the remarks it was evident that a fine spirit existed between employers and employees. A toast to the army, navy and mercantile marine was proposed by W. S. Johnson, and responded to by Lt. Matthews and Capt. Reed. Other toasts were "Our Guests," proposed by Thomas Hall, president of the company, and responded to by Thomas Arnold, and "Our President," proposed by F. H. Fox, secretary-treasurer.

CATALOGUES

Cochrane Precision Meter.—Engineering Bulletin No. 21 deals with the Cochrane precision meter, volumetric type, made by the Harrison Safety Boiler Works, Philadelphia, Pa. A comprehensive description is given of the meter while reference is made to installations on United States battleships. Copies may be obtained on application from Canadian Allis-Chalmers, Ltd., Toronto, agents for Canada.

Industrial Motors.—The second of a series of catalogues of industrial motors has just been distributed by the Westinghouse Electric & Mfg. Co. of East Pittsburgh, Pa. This is known as catalogue 30 and covers the company's complete line of direct current motors and generators for industrial service. After several pages giving general information regarding the ordering, classification and selection of direct current motors there follows complete description, rating and dimensions for type SK commutating-pole motors, various modifications of type SK elevator motors, reversing planer motor equipment, type CD motors, headstock equipment for woodworking plants, type SK and CD motor generators and arc welding equipment. Much new information is given especially on such subjects as arc welding, headstock equipment, motion picture service and battery charging service. The new catalogue is identical in size and will fit the binder for the company's line of catalogues covering supply apparatus and small motors.

CYLINDER LUBRICATION

A powerful microscope will disclose hundreds of irregularities on a bearing surface, no matter how smooth it may appear to the naked eye.

DIXON'S Ticonderoga Flake Graphite

will fill up these minute irregularities and form a smooth, durable veneer of graphite that is practically frictionless.

It will give better lubrication, cut the oil bills in half and eliminate wear and tear.

Send for Booklet No. 222-C telling more about this lubricant and method of successfully feeding dry graphite into cylinders

Standardized Series LEATHER BELTING

Tanned by us for belting use

A Belting Catechism

What are the Advantages of Leather as belting?
Leather is the standard belting material. When properly tanned for belting its surface will grip the pulley in the most effective manner. Good leather belting is economical and reliable. It will transmit power with 98% efficiency.

How can leather belting be made uniform?
The manufacturer must first set up definite standards of quality—and strictly adhere to them. As he cannot secure belting leather in the open market of uniform quality, he must tan his own hides. He must tan them in sufficient quantity to enable him to select for each belt, pieces up to his standard. These pieces must be uniform in weight, stretch. texture, and quality.

Why should belts be rigidly graded?
A belt is no stronger than its poorest part. The quality of leather varies, and unless each belt is carefully graded, dissimilar qualities get into the same belt. Rigid grading *is* uniformity. Grading should be done by expert judges of belt leather quality, according to fixed standards.

Why is there such confusion in leather belting grades?
Because many belt makers have not standardized their belts, but give the buyer any kind of belt he demands. The result is chaotic.

What is Standardized Leather Belting?
Simply belting that is standardized to meet the needs of the different classes of power transmission—instead of being made to meet theoretical specifications. Transmission requirements can be classified into a comparatively few groups, and there is a standardized belt to fit each one. Standardization *can* be applied to belting just as to any other type of machine part or product. It is common sense in belting.

How does Standardized Leather Belting help the belt buyer?
It insures the selection of the proper belt required to speed up machines, to maintain production, to reduce operating expenses, which cannot be accomplished unless the belt user gets the maximum power through his belts. Standardized leather belting effects this for him and enables him to *know* that he is getting the right brand for highest efficiency and greatest economy—maximum service from every belt and every drive.

How does it work?
Let a Graton & Knight representative make an analysis of your belting requirements. Then get the standardized belt for your work, ordering your belting by work to be done rather than by specification. There is no obligation—there may be a great saving for you.

MacLean's Magazine

for JANUARY

Chasing the Submarine—by a Canadian

A CANADIAN, whose name is withheld, in the Motor Boat Patrol Service in the North Sea, tells in the January MacLean's the story of the work and life and triumphs of the Service to which he is attached. It is a fine performance by MacLean's to get this story for the Canadian people. Successes of this sort have made MacLean's go far forward in public favor during past months.

If the horrid and terrible submarine warfare and the conquest of this pest of the deep interest you, learn more about submarines and their capturing in the January MACLEAN'S, and pass on to others the news of this unsigned contribution.

Ships—more ships—and yet more ships

THIS is a very strong article which Miss Agnes C. Laut contributes. As usual she is very well informed. Regarding the duration of the war she voices American opinion when she says that it is likely to be long drawn-out. The United States people are buckling down to a stern struggle. At this time we want very much to read what well-informed, virile thinkers and writers have to say about the war, since things are not any too bright in certain directions. Miss Laut has a good deal to say about the shipping programme of the United States, and certainly she gives facts and sets us thinking as few writers do.

"Jim" by Robert W. Service

A POEM by this strong poet—a poem wrought amid the smoke and hell of battle, yet fanciful and tender. One wonders how men can write fanciful verse amid surroundings that seem so adverse to thinking and writing, yet some gifted can detach themselves and let fancy play; or is it that their minds see through the real and horrible—through the immediate environment into inner things? Whatever it may be, we ought to be glad for the verse that men like Service give us, remembering how and where it is produced.

Adam and Arthur William Brown, Brothers

ADAM BROWN is a Canadian short story writer of large promise. His brother, Arthur William, is one of New York's foremost illustrators. Both brothers have joined their gifts to make Hannibal Helps a mighty good feature of the January MACLEAN'S.

A New Serial by Alan Sullivan

ALAN SULLIVAN'S recent novel, The Inner Door, is being well received. Perhaps we have no better novelist of his type in Canada to-day. He writes books that show introspection and fine analysis. This serial, The Magic Makers, adds venture and mystery to psychological study, and is a rare good thing. Arthur Heming illustrates the story, which begins in Scotland and is transferred to Canada where the stage is set.

The Regular Departments of MacLean's

REVIEW of Reviews, Women at Work, The Business Outlook—are present in goodly measure. Oppenheim's The Pawns Count, Trench Pictures, and first-class illustrations by artists of note help to make the January MACLEAN'S good value for money.

KERR
("New KEYSTONE" Pattern) GATE VALVES

If you have not used any of these New Pattern Valves, specify "KERR" in your next order. We want you to get acquainted with the most reliable valve on the market.

If you have been using them, we are confident that our satisfaction will bring us your repeat orders. These valves will never cause you or your customer the slightest trouble. Their high quality is consistent.

When you buy a "KERR" Valve you get a guaranteed article that is backed by a reliable firm. Many of the largest distributers of valves in Canada have sold "KERR" Valves for over 25 years, and are still recommending them as the "Best Valve." Write us for particulars.

Kerr Engine Co., Ltd., Valve Specialists **Walkerville, Ont.**

6 F Type
Oil Filtering and
Circulating System

Results that Count

The Bowser System makes good results a sure thing.

Wherever it is installed there is more uniform lubrication of machines, without loss of oil; less depreciation of equipment; fewer repair bills; a better spirit among employees, and—increased profits, all of which are good, strong reasons why the Bowser should be in your plant.

The Bowser stores and supplies new oil—collects dirty oil—purifies it, makes it good as new—returns the proper supply to points of use wherever located. Its simplicity, durability, and ease of operation are reasons for its popularity in all well regulated plants.

"Results that Count" always follow its use—we'll be glad to tell you more about it if you drop us a line.

Canadian Association of Stationary Engineers

Incorporated May, 1887 — Incorporated at Ottawa, June, 1917

An organization having as its aims and objects:—

To promote the knowledge of its members in the art and science of Steam Engineering.

The dissemination of information beneficial to the members of the association in the discharge of their calling.

To further and protect the interests of competent engineers, and receive such as members of this organization.

To secure, through proper legislation, the greatest security in operation of steam plants.

To assist unemployed members to secure positions.

To maintain freedom of action between employer and employee.

The members of the Association subscribe to the above in the full belief that ability and knowledge of one's profession are necessary to insure the highest degree of success.

Labor Study Energy

These three essentials have been responsible for the success of the world's greatest men. They are no less essential for yours. We cannot all become great, but this fact does not lessen the necessity for the exercise of these essentials in our individual occupations. Cool, calm, calculating judgment characterizes the successful power house operator of to-day. The demands on the engineer of to-day are many, and the obstacles in his path are great. To assist in the overcoming of these and help the accomplishment of great works, material, moral and educational, is the desire of all our members.

The benefits accruing from association with members of his fraternity, the opportunity to benefit by their experience, and the inspiration to greater effort by reason of their success render membership in this association indispensable to all progressive engineers.

If you are interested in such an organization and live where less than fifteen engineers are located, send for a copy of our constitution and application blanks for admission to nearest branch lodge. If there are more than fifteen engineers in your community, get together and send for particulars regarding formation of a branch lodge.

MARSH and AMERICAN

Steam and Power Driven Pumps and Air Compressors

Marsh and American Pumps are especially adapted for long, hard service because they are *extra heavy* in design and of *extremely rigid construction.* Every unit is built amply strong to withstand 24-hour-a-day service and to stand up under any unforeseen strain which may be placed upon it. Piston rods on the steam pumps are extra large and made of solid bronze. The water ends are equipped with heavy cast bronze removable bushings.

This superior construction not only insures continuous and satisfactory operation, but practically *eliminates expensive shut-downs.* Marsh and American Pumps are the product of over 25 years' experience in the design and construction of high grade pumping machinery. Over 135,000 in actual service throughout the world.

The AMERICAN-MARSH LINE OF CENTRIFUGAL PUMPS is composed of both single and double suction types which are designed for heads up to 125 feet. They are equipped with wide ring oiled bearings and the single suction type has overhanging casing enabling the discharge to be taken at any angle desired.

COOL RUNNING EQUIPMENT

is a matter principally of securing a lubricant that possesses a high lubricating factor and a low melting point. Such a lubricant will never let any bearing become overheated and will assure you of cool running equipment.

ALBANY GREASE

is a pure tallow compound with a high lubricating factor and a low melting point. It can be used on any bearing in your plant and in any kind of grease cup. Send for a trial quantity and an Albany Cup—now.

Albany Lubricating Co.
708-10 Washington Street
NEW YORK

"This core is as good as new, George. Did CLING-SURFACE keep it that way?"
"Sure—this rope ran in the open for 5 years, too."

GEORGE knows!

He had the care of their belts
and ropes.
The firm had a rope drive on the roof
in Buffalo,
exposed to rain, wind, sleet and snow
off Lake Erie,
and smoke from the nearby factories.
These things hurt a rope drive.
They dry out the greases
and the fibres *grate* together.
The "core" is ground to powder.
The rope becomes hollow, limp,
DANGEROUS—it is no longer strong.
But by treating it with CLING-SURFACE
these fibres were kept lubricated.
They did not *grate,*
but *slid,* like a well-oiled bearing,,
and the rope *lasted.*
After *five* years on the roof it was
still good for service
because of CLING-SURFACE.
This semi-liquid
"easy-to-use"
belt and rope treatment
will also prevent slipping
and let you remove some of that tension.
Ask for our Rope Folder P384
or order a can for 60 days' trial.
Remember,
Use CLING-SURFACE
and you won't need belt or rope dressings.

NOTICE

TO

Stationary and Hoisting Engineers

Everyone operating a STATIONARY steam plant of 50 h.p. or over in the Province of Ontario must hold a Stationary Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Everyone operating a HOISTING steam plant working at a pressure of 20 pounds or over, irrespective of horse power, and used for hoisting in structural operations or excavating purposes, in the Province of Ontario, must hold a Hoisting Engineer's Certificate from the Board of Stationary and Hoisting Engineers. Anyone operating such a plant without a Certificate is liable to the penalties set forth in the Stationary and Hoisting Engineers' Act.

Application forms for obtaining STATIONARY or HOISTING Engineers' Certificates, may be had upon applying to the Chairman.

HON. F. G. MACDIARMID, Minister of Public Works and Highways. W. C. McGHIE, Chairman of Board.

BOILER INSPECTION

The Steam Boiler Act, Chapter 252 R.S.O., 1914 With Amendments Chapter 58—6, George V.

STEAM BOILERS.

All Steam boilers constructed for use in Ontario must be built from designs which have been approved and allotted a registration number by the Steam Boiler Branch.

Used boilers, boilers sold or exchanged, and unregistered boilers brought into the Province must be inspected prior to being put into operation.

Notice of repairs to steam boilers, stating the nature and extent of same, must be sent to the Steam Boiler Branch, and should such repairs be considered extensive by the Chief Boiler Inspector, the boilers will require to be inspected.

In each and every case the inspections must be made by Inspectors authorized to inspect boilers under the Steam Boilers Act, who are employed only by the Steam Boiler Branch of the Department of Public Works. Official certificates with the maximum working pressure stated thereon are issued to the owners of the boilers so inspected.

STEAM PIPING.

Drawings and Specifications of all high pressure steam piping must be approved and registered by the Steam Boiler Branch before any work of installation is commenced. The drawings submitted should show clearly the dimensions and layout of the main steam lines. Full particulars should be given as to the material used in the construction of the piping, and all valves and other fittings used in connection therewith must be of approved make.

Any deviation from the above requirements shall be deemed a violation of the Steam Boilers Act.

All communications in this respect should be addressed to the Steam Boiler Branch, Department of Public Works, Parliament Buildings, Toronto.

Even though every

Starrett Hack-Saw

is made of the best material — tungsten steel—and made right in every way, random selection will seldom if ever give best results. Page 208 of Starrett Catalog No. 21CD lists the uses of various Starrett Hack Saws and in this list will be found a saw best suited to every job.

The L. S. Starrett Co.
The World's Greatest Toolmakers
ATHOL, MASS.
42-746

The Wrench of 25% Greater Efficiency

TRIMO PIPE WRENCH

Two new features have been recently added to the Trimo Pipe Wrench, namely Nut-Guards, in all sizes, and unbreakable steel frames, in leading sizes.

The Nut-Guards prevent the accidental rotation of the nut while in use.

These improvements add 25% to the usefulness of the tool.

The Trimo Pipe Wrench is made with wood handles in 4 sizes, 6-in., 8-in., 10-in., 14-in. and in steel handles in all sizes, 6-in. to 48-in. inclusive.

All Trimo Pipe Wrench parts are interchangeable.

The inserted jaw in the handle can be readily replaced when worn, thus adding to the life of the tool.

Nut with Nut-Guards

Inquiries from Importers and Dealers Solicited. Send for Catalogue No. 55.

POWER HOUSE BUYERS' DIRECTORY

If what you want is not listed here write us, and we will tell you where to get it. Let us suggest that you consult also the advertisers' index facing the inside back cover, after having secured advertisers' names from this directory. The information you desire may be found in the advertising pages. This department is maintained for the benefit and convenience of our readers. The insertion of our advertisers' names under proper headings is gladly undertaken, but does not become part of an advertising contract.

Anderson "D" Steam Trap

Here is a Trap that

Won't Blow Steam

It presents an opportunity to combat the abnormal price of fuel.

Re-equip your high and low pressure drip system with the Anderson Model "D" Steam Traps. You will certainly save money in fuel, upkeep and labor.

In tightness, capacity and endurance, they have no equal.

Look at these features compared with any other steam trap:—

1—A counterbalanced Lake Superior float that operates a large area discharge valve. The latter is watersealed against steam leakage at all times.

2—A self-contained perforated strainer is placed near the inlet and prevents the influx of all foreign matter.

3—An outside gauge glass shows at a glance whether the trap is working properly or not.

4—The valve and valve seat can be interchanged to adapt the trap for either high or low pressure.

5—All parts are interchangeable and readily accessible.

6—The self-contained by-pass can be opened by a half turn of the conveniently located handle.

At your service in laying out your new drip system. No obligation for useful suggestions.

The V. D. Anderson Co.

1935 West 96th St., Cleveland, Ohio

It Can't be Beat

for direct drives, straight or crossed. It is built of solid woven cotton, proof against dust, oil and heat—edges proof against shifter wear. Can be used practically everywhere that leather can be used.

Scandinavia BELTING

Without obligating you in any way, we will be glad to help you end your belt troubles.

Write for advice and the monthly booklet—"Belts".

SCANDINAVIA BELTING — FEDERAL ENGINEERING & SUPPLIES LIMITED — TORONTO

Federal Engineering Co. LIMITED

172 John St., TORONTO

Morehead

Back to Boiler SYSTEM

Save 8 to 20% of fuel

and increase the efficiency of your steam plant. The Morehead System takes condensation from steam lines and returns it to the boilers as pure, HOT feed water. Better service from steam lines—actually increases efficiency of steam heated machinery. Many users report that steam heated equipment is made to produce 50% greater volume.

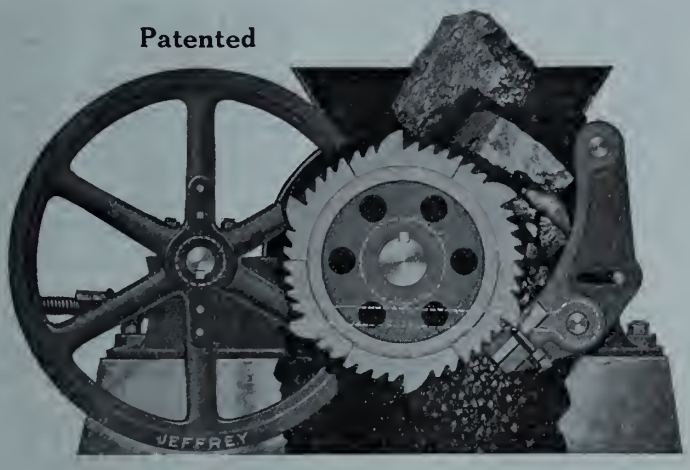
SUNDAY DISPATCH. SUNDAY, OCTOBER 7, 1917.
Shortage of Electricity
For Power, Light and Street Railway Purposes
Electric Power Shortage
The electric power situation in and the surrounding territory served by this company has become more acute. This is due to the fact that the existing equipment in our power stations cannot be operated at its full capacity because we have been unable to procure a good grade of coal. However much we may regret our inability to meet the demands upon us—and we most certainly do regret it—the situation must be squarely faced and steps taken to conserve the supply of electricity.
We request those who use electricity for power purposes to give their most earnest consideration to ways in which they can saving of current in their business.
who use electricity for lighting fewer lights. Use only were used.
Our Coal Troubles
The coal we are now receiving is of the most inferior grade we have ever had experience with. Our firemen jokingly refer to it as "fireproof" coal because it is so full of dirt that it will barely catch fire. In fact, some actually had corn growing in it as it stood in the car when received, and tests made of the coal have shown it to contain as high as 26 per cent. of non-combustible material.
It has been due to this fact that several times recently we have been forced to discontinue service to power customers, to operate cars at half speed for short periods and to operate a reduced number of trippers during the rush hours. The poor grade of coal makes it utterly impossible to operate our boilers at capacity and lowers the output of our power station system.
Our Plans to Improve Service
With a view to bettering the fuel situation in our power stations we have acquired the use of a crushing plant in the city which will enable us to reduce to smaller sizes for use in our stokers lump and run-of-mine coal, and we have men continually in the coal fields using all their efforts to secure such coal.
The present serious situation prevails throughout the country—this community is not alone in difficulty, but this company, without help, can not attain the desired results. Relief can come only with your immediate and persistent co-operation.
Power & Light Co.
A Jeffrey Single Roll Crusher

Are You Facing a Similar Situation?

If so, why not Crush your Run-of-Mine or Lump Coal right in your own Power House with a

Patented



JEFFREY

SINGLE ROLL

Coal Crusher

One operation reduces Lump or Run-of-Mine Coal to the proper size for maximum heat efficiency in stokers.

Bulletin No. 141-4 fully describes this machine — tells what it has done for others. Send to-day for your copy.

Every Electrical Man Wants These Books and we ship them for your inspection FREE

Flexible Covers — Handy Pocket-Size Volumes

10 Numbers — 3500 Pages — 4700 Pictures

$1 A Volume

$1 A Month

Just what you need to know to succeed in ELECTRICITY

EVERY electrician, every engineer, every mechanic should know about these wonderfully helpful instructive books, which give in plain words a complete working knowledge of electrical engineering in all its branches.

You run into some new electrical problem almost every day. The information you need to help you in your everyday work is in

HAWKINS ELECTRICAL GUIDES

These books place electricity at your finger ends. They cover every imaginable subject, principle, theory, problem, trouble, and way of doing things electrically. Every subject is indexed so that you can turn right to it. They are a study course and a reference guide in one, written in plain everyday language—no wasted words—only what you need to know—chock full of up-to-the-minute electrical knowledge. The guides are a complete course in electrical engineering. They will help you in every detail of the day's electrical work. You can't ask an electrical question that Hawkins Guides can't answer.

What Electrical Men Say

Helped Him Make Good.

"It is only right for me to recommend highly the Hawkins Guides, for they have been of the greatest assistance to me in placing me in my present position as Superintendent of Construction Department of one of Ohio's largest Electrical Companies. I would like to see every man have a set of Hawkins Guides."

Geo. Knecht, Columbus, Ohio.

In the Naval Electrical Dept.

"The Hawkins Guides are great help to me in the Naval Electrical Department, which they cover very thoroughly." C. J. Cornell, U.S. Receiving Ship, Brooklyn, N.Y.

Superintendent

"I am now superintendent of the Dunnville Hydro-Electric Systems, and Hawkins Guides were a great help to me in holding down a responsible position."

W. E. Swartz, Dunnville, Ontario.

Wireless Operators

"I have worked wireless for ten years—but I wish I had these books years ago, as they have saved me a great deal of trouble." H. Marsball.

Steamer M. & B. No. 2, Walkerville, Ont.

Pocket-Size Flexible Covers

The books are small enough to slip into your coat pocket—handsomely bound in flexible black covers.

You can carry each volume with you until you have mastered its contents. 3,500 pages of actual information and 4,700 illustrations. Once you see these books and put them into actual use you will never again want to be without them. Try it at our expense.

SEND NO MONEY

It will cost you nothing to receive these books—to look them over—ask them all the questions you can think of—use them in your work—study them—pick up some information that will increase your earning ability. We will ship you the entire set of 10 volumes entirely FREE.

This is a sign of our confidence in the guides. Pure gold does not object to being tested. Keep them for seven days and if you do not decide that you can't get along without them, return them to us and owe us NOTHING.

When you decide to keep them you only have to pay $1.00 down and remit the balance of $9.00 on the easy payment of $1.00 a month till paid for.

Use this coupon to get the books. It will pay you many times over.

THEO. AUDEL & CO.

72 Fifth Avenue New York, N.Y.

READ THIS PARTIAL LIST OF CONTENTS.

No. 1 Contains 348 pages. 388 illustrations. Electrical signs and symbols—static current electricity—primary cells—conductors and insulators—resistance and conductivity—magnetism—induction coils—dynamo principles—classes of dynamos—armatures—windings—commutation—brushes, etc.

No. 2 Contains 348 pages, 394 illustrations. Motor principles—armature reaction—motor starting—calculations—brake horsepower—selection and installation of dynamo and motors—galvanometers—standard cells—current measurement—resistance measurement—voltmeters — wattmeters — watt hour meters—operation of dynamos—operation of motors, etc.

No. 3 Contains 300 pages 423 illustrations. Distribution systems—wire and wire calculations—inside, outside and underground wiring—sign flashers—lightning protection—rectifiers—storage battery systems, etc.

No. 4 Contains 270 pages, 379 illustrations. Alternating current principles—alternating current diagrams—the power factor—alternator principles—alternator construction—windings, etc.

No. 5 Contains 320 pages, 614 illustrations. A. C. Motors—synchronous and induction motor principles—A. C. commutator motors—induction motors, transformers; losses, construction, connections, tests—converters—rectifiers, etc.

No. 6 Contains 298 pages, 472 illustrations. Alternating current systems—switching devices—circuit breakers—relays—lightning protector apparatus—regulating devices—synchronous condensers—indicating devices—meters—power factor indicators—wave form measurement—switch boards, etc.

No. 7 Contains 316 pages, 379 illustrations. Alternating current, wiring power stations—turbines: management, selection, location, erection, testing, running, care and repair—telephones, etc.

No. 8 Contains 332 pages, 436 illustrations. Telegraph—simultaneous telegraphy and telephony—wireless—electric bells—electric lighting—photometry, etc.

No. 9 Contains 322 pages, 627 illustrations. Electric railways—electric locomotives—car lighting—trolley car operation — miscellaneous applications — motion pictures—gas engine ignition—automobile self-starters and lighting systems, electric vehicles, etc.

No. 10 Contains 513 pages, 599 illustrations. Elevators—cranes — pumps — air compressors—electric heating—electric welding—soldering and brazing—industrial electrolysis—electro plating—electro-therapeutic—X-rays, etc.

Also a complete 126-page ready reference index of the complete library. This index has been planned to render easily accessible all the vast information contained in the 10 electrical guides. There are over 13,500 cross references. You find what you want to know instantly.

MILL SUPPLY DEPARTMENT **BEVERIDGE PAPER COMPANY, LIMITED**
17-19 ST. THERESE STREET, MONTREAL

MANUFACTURERS:—Now is the time for your Boiler Repairs—you can SAVE money and get UTMOST SATISFACTION by using our Boiler Specialties. NO SKILLED LABOR REQUIRED. Equally good for large or small repairs.

PROTECTO—Boiler Preservative—the king of boiler compounds, removes scale, prevents foaming and priming and absolutely guarantees pure steam.

PROTECTOCOAT—Elastic Paint for coating boiler brickwork—fills up all cracks, keeps out all cold air. The saving in fuel will more than repay cost.

PLIBRICO—A one-piece Plastic Jointless Furnace Lining for repairs, arches, bridge walls, etc.; does not break, crack or shell off like ordinary firebrick; forms a solid block. No skilled labor required to apply.

PLIBRICO BOND—High Temperature Cement—made in three grades. Does not burn out like ordinary fireclay. Guaranteed to stand 3100° F.

ENQUIRIES SOLICITED—FULL PARTICULARS ON APPLICATION.

Local Representatives:—J. M. Allen, 65 Bloor St. W., Toronto, W. Reid, 27 Celebration St., St. John, N.B., P. H. Cowan & Co., St. Johns, Nfld.

Mention This Paper When Writing Advertisers

Don't buy that New Electrical Apparatus Just Yet

WE can supply you with high-grade apparatus that has been slightly used and discarded through no fault of its own, at an **immense saving in cost.** For instance, in many cases we take over entire plants simply because of changed conditions such as increased capacity, change of system, etc.

EVERYTHING IS OVERHAULED AND REFINISHED BY US AND **GUARANTEED** AS GOOD AS NEW, BOTH ELECTRICALLY AND MECHANICALLY.

Our catalogs of offerings should be in the hands of every power plant superintendent each time they are gotten out, and it will be worth while for anyone interested in this class of power plant equipment to be on our mailing list to receive all offerings.

Nearly all of the principal power, lighting and street railway plants in the United States are our customers.

WRITE FOR OUR LATEST CAT ALOG of **Power House Equipment, Street Cars, Motors, Hoists, Compre ssors, etc.**

MACGOVERN & COMPANY, Inc.

Continuously Efficient Service

on the most troublesome lines is obtained only thru the use of

Homestead
Quarter Turn
Valves

If you want to know what a real serviceable valve can do for you in your Plant, just try a "Homestead."

Homestead Valves will last several times as long as the ordinary valve and will save their own cost shortly after installation through eliminating wastes and leakages.

Thousands of satisfied customers daily testify to its efficiency and back up their belief in this money-saving valve by giving us repeat orders.

We will cheerfully demonstrate the superiority of the Homestead Valve by sending you one for trial.

Write to-day.

Homestead Valve Mfg. Co.
HOMESTEAD, PA.

STOPS

Wear and Tear of Water in Pipes

It is the hammering or concussion of water admitted to your pipes at greatly varying pressures that makes repairs to your pipes and fittings so often necessary and costly.

Curtis Water Pressure Regulator

Stops all Wear and Tear

The Curtis Regulator—not your pipes—meets the fluctuating outside pressure and steps it down to a pressure that will not cause hammering in your pipes. Delivery of water into your service pipes at any desired pressure is guaranteed.
The Curtis Regulator is proof against rust and clogging. It is made of the most durable material, and will serve without trouble for years

Write for Facts and Prices.

Inglis Boilers

The Standard

for materials and of workmanship, workmanship, value and efficiency for over half a century. They ensure a lifetime of service with a minimum of repairs.

We make boilers for all kinds of service. Inglis installations include many of the largest steam plants in Canada—and every installation is a working testimonial of their efficiency and economy.

We are also sole Canadian makers of Erie City Water Tube Boilers. Vertical and Horizontal. Our representatives will be pleased to show installations of our different types of boilers to prospective customers.
